**RE: Final Remedial Action Plan
Former Santa Rosa Manufactured Gas Plant
111 Santa Rosa Avenue
Santa Rosa, California**

Dear Ms. Lamb:

On behalf of Pacific Gas and Electric Company, Terra Pacific Group Incorporated is pleased to submit the above-referenced Final Remedial Action Plan for Pacific Gas and Electric Company's Former Santa Rosa Manufactured Gas Plant. If you have any questions or comments, please do not hesitate to call me at (760) 213-5782.

Respectfully submitted,

Terra Pacific Group Incorporated

Murray Wunderly PG, CHG
Principal

Enclosure: Final Remedial Action Plan (electronic copy)

EXECUTIVE SUMMARY

This Final Remedial Action Plan (RAP) addresses soil and groundwater impacts resulting from operation of the former Santa Rosa Manufactured Gas Plant (MGP) in Santa Rosa, California (Figures 1 and 2) from 1877 to 1924. The majority of the former Santa Rosa MGP property (the Site) currently consists of a parking lot for the commercial office building located at 111 Santa Rosa Avenue.

Investigation began at the Site in July 1986. To date, samples have been collected at more than 300 locations; many of these locations include samples from multiple depths. Groundwater monitoring was originally conducted sporadically following installation of the first wells in 1988. Since 1997, groundwater has been monitored twice yearly, with the exception of 2006 when only one groundwater monitoring event was conducted.

Early removal of impacted soil took place over several events in late 1987 and mid-1988 prior to Site development. In 2004, PG&E conducted remediation activities in Santa Rosa Creek and the adjacent north bank directly to the south of the Site in association with the development of the Prince Memorial Greenway (PMG) by the City of Santa Rosa Department of Public Works. In 2006, EBA Engineers excavated and removed two underground storage tanks (USTs) from the parking lot area of the Site. A former redwood gas holder at the Site was remediated using electrical resistance heating (ERH) in 2009 and 2010. Due to the large volume of coal tar extracted during ERH operations (approximately 55,000 gallons), geotechnical stabilization of the soils in this area was necessary to prevent further settlement of the ground surface. In situ soil mixing (ISSM) was implemented in the vicinity of the redwood gas holder in 2012 and 2013 using large diameter auger soil mixing and jet grouting. Following ISSM, an engineered cap was installed over the entire treatment area. In October 2011, targeted soil excavation activities were conducted to remove shallow soil with elevated lead concentrations in the area south of the entrance to the underground parking garage. Soil excavation activities were also conducted in 2013 to remove impacted shallow soil in the planter areas in and around the parking areas. Following completion of the remediation activities conducted through 2013, the parking lot at the Site was restored to pre-remediation conditions.

A Screening-Level Human Health Risk Assessment (SLHHRA) was prepared by Iris Environmental to determine whether levels of chemicals remaining in soil at and around the Site could pose a risk to human health based on current and potential future property uses. The results of the SLHHRA were used to identify areas where remedial/mitigation measures and/or risk management may be appropriate, with the overall goal of long-term protection of human health. Three areas were evaluated in the SLHHRA, including the on-site property (111 Santa Rosa Avenue; APNs 010068020 and 010068021), the 438 First Street Property (APN 010068019), and off-site public Right of Way (ROW) areas consisting of all other areas adjacent to the Site (Figure 2). Based on the current and assumed hypothetical future uses for each of these areas, the populations included in the SLHHRA consisted of the following:

- Current commercial worker (also evaluated as protective of infrequent visitors);

- Hypothetical future commercial worker (including short-term construction/intrusive workers); and,
- Hypothetical future resident.

Under current conditions, the potential pathways through which commercial workers could be exposed to compounds of potential concern (COPCs) in soil are considered incomplete or insignificant. Therefore, the current conditions are fully protective of the health of current commercial populations and no further remedial or mitigation measures are warranted. Risk management measures, such as a cap maintenance/soil management plan and deed restrictions, are warranted to ensure that conditions remain protective of human health. Although it is not anticipated that any of the areas evaluated would be used for future residential use, soil impacts within the upper 10 feet were evaluated against residential use criteria and were determined to exceed acceptable levels in at least a portion of each area. Accordingly, risk management measures that restrict future residential use of these areas are also warranted.

Several Feasibility Studies were conducted for soil and groundwater between 2006 and 2015. The overall proposed soil and groundwater remedy selected included the following components:

- Removal of the former USTs in the parking lot west of the building entrance;
- Remediation of the redwood gas holder;
- Removal of the existing on-site UST (on hold pending land use changes);
- Targeted excavations to remove heavily impacted soils in the vicinity of the former and existing USTs (on hold pending land use changes), and shallow soils in the area south of the underground driveway entrance;
- Long-term groundwater monitoring;
- Maintaining current cap; and,
- Deed restrictions.

The majority of these remediation components have been completed. However, removal of the existing steel UST, and targeted soil excavation beneath the existing UST and the two former USTs have been placed on hold pending land use circumstances that will allow for additional significant land use disruption. PG&E will continue to search for a suitable method to remove the existing steel UST that would allow for removal of the UST and its contents without causing a nuisance condition for the building tenants or the community.

An O&M Plan for post-remediation groundwater monitoring and cap inspection and maintenance activities will be prepared and implemented as part of the post-remediation monitoring program. In addition the O&M Plan will also include the details of the five-year reviews that will be conducted.

Groundwater monitoring is proposed at 14 monitoring well locations semiannually. These wells constitute a subset of existing wells and were selected to provide a good spatial distribution of groundwater sample locations including the most downgradient wells. These wells are generally screened within a hydrogeologic unit where migration of contaminants to Santa Rosa Creek, if it were to occur, would most likely be observed.

Five-year reviews will be conducted following the Regional Water Quality Control Board (RWQCB) approval of the proposed O&M Plan. The reviews will include a Site inspection, technical assessments of the ongoing monitoring, presentation of opportunities for optimization of the post-remediation program, any changes to conditions and land use or standards, and any updated risk calculations and assessments, where relevant. The reviews will also include information on any new technologies and/or methods that may be suitable for addressing the existing UST without causing a nuisance condition for the building tenants or the community.

Land Use Covenants (LUCs) will be pursued for the Site and the 438 First Street Property, and an agreement will be pursued with the City of Santa Rosa, to ensure Site occupants (current and future) are aware of areas where chemical residuals remain in soil or groundwater that may have an adverse health impact if disturbed without taking proper precautions. The location of the restricted areas will be surveyed and a legal description prepared for each property. Areas lying outside the restricted areas would not require special precautions unless unknown contamination is encountered.

The RAP will be subject to a 30-day public comment period to solicit community input. The RWQCB may host a public meeting to solicit feedback, as warranted. At the close of the public comment period, the RWQCB will review and respond to all public comments prior to making a decision to approve, modify or deny the RAP.

1.0 INTRODUCTION

This Final Remedial Action Plan (RAP) was prepared by Terra Pacific Group (TPG) for Pacific Gas and Electric (PG&E) to address soil and groundwater impacts at the former Santa Rosa Manufactured Gas Plant (MGP) located at 111 Santa Rosa Avenue, Santa Rosa, California (Figures 1 and 2).

1.1 SITE LOCATION AND DESCRIPTION

The Site is located in the City of Santa Rosa, California located between First Street and Santa Rosa Creek, and B Street and Santa Rosa Avenue (Figures 1 and 2). The Site was formerly the location of an MGP constructed by the Santa Rosa Gas Light Company. The MGP eventually became part of the PG&E system and PG&E sold a portion of the property to the City of Santa Rosa in 1978, and the remaining portion to the 137 Santa Rosa Group Partnership in 1987. A commercial office building overlies a portion of the Site. The two most eastern parcels occupied by the commercial office building were not part of the MGP and were never owned by PG&E.¹

1.2 HISTORICAL SITE USAGE

In 1876 and 1877, an MGP was constructed at the Site (PG&E, 1986). The MGP was constructed by the Santa Rosa Gas Light Company and originally used coal as a feedstock. The plant was converted to use oil feedstock by about 1904 and was acquired by PG&E in 1908. The manufacturing of gas ceased in 1924 and all above ground gas manufacturing structures and equipment were subsequently removed. Following closure of the MGP, PG&E constructed a new facility for natural gas distribution that was in operation until at least 1969. In 1987, the Site was vacant when the 137 Santa Rosa Group Partnership (137 SR Group) acquired it from PG&E and constructed the existing commercial building at 111 Santa Rosa Avenue. The majority of the MGP operations were conducted in the area presently covered by the parking lot of the commercial building (Figure 2).

1.3 SITE GEOLOGY AND HYDROGEOLOGY

The Site is located in an urban commercial development located in the Santa Rosa Plain, a northwest trending alluvial valley. The Site is directly underlain by artificial fill material that rests on Recent-age alluvial sediments composed of varying amounts of clay, silt, sand, and gravel. The alluvial sediments overlie the Plio-Pleistocene Huichica and Glen Ellen Formations. These formations are composed of poorly consolidated, interbedded silty clay, sand, poorly cemented conglomerate and gravel of fluvial origin. The lower part of the Glen Ellen Formation is tuffaceous (volcanic) in part. The Glen Ellen Formation overlies the Tertiary Sonoma Volcanics. The Sonoma Volcanics consist of lava flows, tuffs, agglomerates and intercalated sediments of volcanic debris (Cardwell, 1958). The Franciscan Complex forms the basement of the region. The Franciscan Complex in this area consists

¹ The Site is identified by assessor parcel numbers (APNs) 010068017 and 010068018. APN 010068018 is the portion of the Site that was sold to the City of Santa Rosa in 1978. The remaining APN, 010068017 was later split into two parcels, 010068021 and 010068022. The commercial office building overlies three separate parcels including APN 010068021, formerly part of the MGP, and APNs 010068010 and 010068020 which were not part of the MGP and were never owned by PG&E.

dominantly of sandstone and shale with minor greenstone, blueschist, limestone, and chert. The Franciscan is pervasively sheared and split from tectonic activity (Cardwell, 1958).

At the Site, the thickness of fill material thins significantly northward from the creek. Coarser grained alluvial material is most prevalent near the creek with finer grained material becoming more prevalent northward from the creek.

The Santa Rosa Plain is an approximately 96 square mile basin drained by Santa Rosa Creek and its tributaries (DWR, 1975). The North Coast Regional Water Quality Control Board has identified the Site as part of the Santa Rosa Creek Hydrologic Subarea of the Russian River Hydrologic Unit. Santa Rosa Creek, the nearest surface water feature, is located on the southern boundary of the Site. Santa Rosa Creek flows in a westerly direction until it reaches the Laguna de Santa Rosa and then to the Russian River.

Cardwell (1958) describes the hydrogeology beneath the Site vicinity as dominated by the alluvium associated with Santa Rosa Creek. Regional groundwater flow is generally to the west-southwest towards the Laguna de Santa Rosa (Cardwell, 1958).

Groundwater at the Site occurs at approximately 20 feet below ground surface (bgs), with a general south to southwesterly gradient towards Santa Rosa Creek. Groundwater levels are generally responsive to seasonal variations in precipitation and may vary as much as a few feet seasonally. As part of the Prince Memorial Greenway (PMG) restoration project, an approximately 350-foot-long section of the creek bed, west of the Santa Rosa Avenue Bridge, was lined with riprap and grout. This low permeability lining in the creek bed limits groundwater discharge to the creek to the south of the Site and causes groundwater beneath the creek to flow west beyond the end of the creek bed lining prior to discharging to the creek. The most recent groundwater elevation contours map is shown in Figure 3 (TPG, 2015b)

1.4 PREVIOUS ENVIRONMENTAL INVESTIGATIONS

Investigation of the former MGP site began in July 1986 with the collection of sixteen surface soil samples by PG&E (PG&E, 1986). To date samples have been collected from more than 300 locations; many of these locations included samples from multiple depths. Figure 4 shows the location of investigation and confirmation samples used to evaluate Site conditions. Historical samples from locations where remediation has been conducted were excluded from the current dataset because the samples have either been excavated or treated and are no longer representative of current Site conditions.

Following acquisition of the property in 1987, the 137 SR Group conducted a series of soil and groundwater investigations to evaluate the extent of soil and groundwater impacts prior to development of the Site. In 2002, prior to the construction of the PMG, the City of Santa Rosa collected soil and grab groundwater samples from the north bank of the Santa Rosa Creek including six groundwater samples collected from the bottom of the creek, immediately adjacent to 111 Santa Rosa Avenue. In 2003 ENV America conducted a focused investigation of soil and groundwater in the Creek bed (ENV, 2005a). In 2005, additional monitoring wells were installed as part of an

investigation to further delineate groundwater impacts and monitor water levels in areas where groundwater levels have not historically been monitored (ENV 2005b). Groundwater monitoring was originally conducted sporadically following installation of the first wells in 1988. Since 1997, groundwater has been monitored twice yearly, with the exception of 2006 when only one groundwater monitoring event was conducted. The groundwater monitoring data from these events are included in Appendix A.

Various additional field investigations were conducted from July 2006 through April 2007. This work was conducted in accordance with the *Work Plan for Subsurface Investigation of Redwood Tank Area* (TPG, 2006b), the *Work Plan for Additional Subsurface Investigation* (TPG, 2006c), and the *Groundwater Monitoring Plan* (TPG 2007a). In July 2006 drilling was conducted in the vicinity of the former redwood gas holder. In November 2006, drilling was conducted on the neighboring property to the west of the former MGP and three vapor extraction wells were drilled within the footprint of the former redwood gas holder. In December 2006, a pilot scale Soil Vapor Extraction (SVE) test was conducted in the footprint of the former redwood gas holder to evaluate the effectiveness of SVE as a remedial technology for the redwood gas holder area. In February 2007, an investigation was conducted to evaluate previously identified subsurface anomalies, investigate the existing underground storage tank (UST) at the Site, evaluate potential oil feed lines entering the Site from the north, install one additional downgradient monitoring well, and conduct aquifer testing at various locations. In April 2007, an additional geophysical investigation was conducted at the Site. The results from these various investigation activities were summarized in the *Additional Subsurface Investigation Report* (TPG, 2007b).

Field investigations were also conducted from January to March 2008. The work performed was conducted in general accordance with the *2008 Workplan for Additional Subsurface Investigation* (TPG, 2008a), and the *Addendum to the 2008 Workplan for Additional Site Investigation* (TPG 2008b). The primary investigation phases conducted between January and March 2008 included:

- A subsurface investigation along the southern portion of the Site and the PMG;
- A subsurface investigation of soils adjacent to a large diameter storm drain located on the 438 First Street Property to the west of the Former MGP; and,
- A trenching investigation to further evaluate the condition and contents of the 10,817-gallon UST in the southern portion of the Site.

Results from these various investigation activities were summarized in the *2008 Site Assessment Report* (TPG, 2009a).

Field investigations were also conducted from June to August 2009. The work performed was conducted in general accordance with the *Redwood Tank Downgradient Well Installation Workplan* (TPG, 2009b), the *CPT/MIP Drilling Investigation Workplan* (TPG, 2009c), and the *Addendum to Redwood Tank Downgradient Well Installation Workplan* (TPG 2009d). The primary investigation phases conducted between June and August 2009 associated with the groundwater investigation downgradient of the redwood gas holder included:

- Installation of groundwater extraction and monitoring wells downgradient of the redwood gas holder (RW-1 through RW-5), along the PMG further downgradient

- from the redwood gas holder (PM-1 through PM-6 and MW-23), and immediately downgradient from monitoring well MW-14 (MW-22);
- Destruction of monitoring well MW-19 and installation of shallow and deep replacement wells;
- Groundwater sampling activities at monitoring wells in the vicinity of, and downgradient of, the redwood gas holder;
- Completion of cone penetration test/membrane interface probe (CPT/MIP) soil borings and hydropunch borings downgradient of the redwood gas holder; and,
- Completion of step drawdown and aquifer testing in selected monitoring wells downgradient of the redwood gas holder.

Results from these various investigation activities were summarized in the *Groundwater Investigation Downgradient of the Redwood Tank Report* (TPG, 2010).

In 2011 and 2012, three phases of soil sampling were conducted in the planter areas on-site, and adjacent to the Site, in accordance with three approved Workplans (TPG, 2011a; 2011b; and 2011c). Soil samples were collected from 34 locations within the planter areas to characterize the shallow soil. Results from the sampling were summarized in the *Planter Area Soil Excavation Workplan* (TPG, 2012b).

1.4.1 Inventory of Groundwater Wells

Monitoring wells were first installed at the Site in 1987. Since then, additional wells have been installed and several wells have been destroyed during various investigations. Existing groundwater monitoring wells include MW-1, MW-2, MW-7 through MW-23, and EBAMW-1 and EBAMW-2. Monitoring well MW-6 was never drilled. Monitoring wells MW-3, MW-4, and MW-5 were destroyed and are no longer available for monitoring. Nine of the existing wells, MW-10 through MW-18, were installed during the Supplemental Groundwater Investigation conducted in March of 2005. These wells were installed to further evaluate potential groundwater impacts and monitor water levels in areas where groundwater levels had not historically been monitored. Monitoring well MW-19 was installed in November 2006 downgradient of the former redwood gas holder area, and was replaced in June 2009 with shallow and deep completion wells MW-19S and MW-19D. MW-20 was installed in the PMG to the southwest of the 111 Santa Rosa Avenue property to monitor groundwater conditions downgradient of the Site. An additional monitoring well, MW-21, was installed in March 2008 to monitor groundwater conditions adjacent to the Santa Rosa Creek immediately south of the Site. EBAMW-1 and EBAMW-2 were installed in November 2008 to assess impacts to groundwater related to two former USTs in the parking area adjacent to the building. Well MW-22 was drilled in June 2009 as a monitoring point downgradient of well MW-14, which has historically had small amounts of light non-aqueous phase liquid (LNAPL) floating on water in the well. Well MW-23 was installed in August 2009 to serve as a monitoring point downgradient of the redwood gas holder between MW-19S/D and MW-20.

In addition to the groundwater monitoring wells described above, a series of wells were installed during remediation at the redwood gas holder (ERH-MW1 through ERH-MW4, and RW-1 through RW-5) to monitor and/or extract groundwater during remediation activities. A series of six additional

potential extraction wells (PM-1 through PM-6) were installed along the Prince Memorial Greenway (TPG, 2010).

As remediation in the vicinity of the redwood gas holder progressed, additional monitoring wells were destroyed. Monitoring well ERH-MW-2 was destroyed in August 2009 because it became plugged with tar. Monitoring wells ERH-MW-1, ERH-MW-3, ERH-MW4, and RW-2 through RW-5 were destroyed between March and April 2012, prior to the final remediation phase at the redwood gas holder, because the wells were located within the area where the in situ soil mixing (ISSM) remedy was planned. Monitoring well MW-18, located in Santa Rosa Avenue, was also destroyed at this time because the well had been damaged by traffic. Two new extraction wells, RW-2R and RW-3R were installed downgradient of the redwood gas holder, outside of the treatment area as replacement wells. In April 2013, well RW-1 was destroyed to accommodate site restoration activities in that area of the Site.

1.5 PREVIOUS REMEDIAL MEASURES COMPLETED

The following sections summarize the various remedial measures that have been completed to date.

1.5.1 Pre-development Excavations

Early removal of impacted soil took place over several events in late 1987 and mid-1988 prior to development of the Site (ATT, 1988). One excavation, located in the northern portion of the Site, where the former redwood gas holder was located, was approximately 20'x20' and 15' deep. A second excavation, located north of the underground high pressure gas line in the central portion of the Site, was approximately 40'x20' and 15' deep. The intent of this excavation was to remove material identified at the time as coal tar residue and Bunker "C" oil; however, the removal of contamination was ultimately limited by the presence of utilities in the area. The extent of a third excavation is not exactly known but based on drawings of the excavation appears to comprise a circular area approximately 40 feet in diameter where a brick lined vault was uncovered and subsequently removed in the northern portion of the Site near the northwest corner of the building (ATT, 1988). Excavated soil from all of these excavations was profiled and subsequently disposed of off-site. The location of these excavations is shown on Figure 5.

1.5.2 Remediation within Santa Rosa Creek as Part of the PMG Construction

In 2004, remediation activities were conducted in Santa Rosa Creek and the creek's north bank directly to the south of the Site in association with the development of the PMG. The remediation activities were conducted by PG&E and were completed as part of the PMG Project implemented by the City of Santa Rosa Department of Public Works (the City) in 2004. This phase of the PMG Project entailed the restoration of a 1/2-mile section of Santa Rosa Creek extending eastward from Highway 101 to the Santa Rosa Avenue Bridge. Creek work adjacent to the site was permitted by the California Department of Fish and Game between June 15 and October 15, 2004.

As part of the remediation activities, a total of 160 linear feet of sheet pile shoring was installed to approximately 36 feet deep to the west of the utility bridge along the creek bank immediately south of the concrete double-retaining-wall structure constructed for the PMG.

PG&E excavations in the creek bed extended approximately 100 feet on either side of the utility bridge (to the east and west) at depths ranging from 4 feet to 12 feet deep. The excavations were backfilled with a concrete slurry (Figure 5). Approximately 3,200 tons of impacted soil were excavated and transported for off-site disposal. Additionally, an approximately 350-foot-long section of the creek bed west of the Santa Rosa Avenue Bridge (including the PG&E remedial excavation areas) was subsequently lined with riprap and grout as part of the PMG restoration project.

Excavation and confirmation sampling activities were conducted under the oversight of the RWQCB and the Santa Rosa Fire Department (SRFD). Confirmation soil samples were collected from the bottom and sidewalls of the excavated areas for laboratory analyses prior to backfilling. A post-remediation ecological risk assessment was conducted using the analytical results of the confirmation samples representing soil remaining (ENV, 2005a). The results of this risk assessment indicate that post-remediation Site conditions pose little or no risk to aquatic organisms via a surface water or sediment contact exposure pathway.

The remediation activities effectively reduced the volume of MGP-related wastes beneath the creek bed to the extent practicable and feasible. The sheet pile shoring and grout slurry, in conjunction with the creek bed lining, will control the potential migration of remaining MGP-related wastes from the former MGP site to the creek. The remediation activities were documented in the *Soil Remediation Completion Report* (ENV, 2005a).

Remediation activities at the adjacent Boyett property to the south of the Santa Rosa Creek were also conducted by Granite as part of the 2004 City PMG project, but unrelated to the PG&E remediation activities. The remediation activities at the Boyett property included excavation of soil impacted by refined petroleum products in areas extending from the Boyett property to the south side of the creek centerline. The remedial action for the Boyett property also included the installation of a 400 foot long cut-off wall (sheet pile shoring) along the south side of the creek bed downgradient (north and northwest) of the Boyett property.

1.5.3 Removal of Two Underground Storage Tanks

In 2006, EBA Engineers excavated and removed two USTs from the parking lot area of the Site. The location of the former USTs is shown on Figure 5. The tanks were approximately 7 feet in diameter by 35 feet long with an approximate volume of 10,000 gallons. The USTs were removed from the excavation under the direction of the SRFD. Both tanks were transported under manifest to Ecology Control Industries in Richmond, California, a licensed disposal facility (EBA, 2006).

The final dimensions of the UST excavation were approximately 20 feet wide by 40 feet long by 12 feet deep. Approximately one foot of petroleum hydrocarbon impacted soil was initially removed from the excavation. Confirmation sidewall and bottom samples were collected from the pit center

and bottom at depths of 16 and 20 feet bgs. All of the soil samples were collected directly from the excavator bucket using 2-inch diameter by 6-inch long brass tubes.

Excavated soil was transported for off-site disposal and the excavation pit was lined with plastic sheeting and backfilled to grade with clean import fill material. The backfilled soil was compacted in place and the asphalt surface was paved to match the existing surface. The UST removal activities are documented in the *Report of Investigation UST Removal* (EBA, 2006).

1.5.4 Redwood Gas Holder Remediation – Electrical Resistance Heating

In September 2007, a Feasibility Study (FS) was prepared to evaluate various potential remedial alternatives for mitigation of soil and groundwater impacts in the vicinity of the redwood gas holder at the Site (TPG 2007c). The FS was approved by the RWQCB in a letter dated November 13, 2007 to Mr. Robert Doss of PG&E and Mr. Paul Louie of Upway Properties. Based on the results of the FS, Electrical Resistance Heating (ERH) was selected as the preferred remedial alternative for the redwood gas holder.

An *Engineering Design Report for Redwood Tank Electrical Resistance Heating* (EDR) was subsequently prepared on behalf of PG&E by TPG and TRS Group, Inc. (TRS) (TPG, 2008c). The EDR detailed the ERH system engineering and design, described the various planning and installation activities, outlined key operation and maintenance requirements, and presented the sampling program for monitoring progress. All necessary permits for the ERH system were obtained and the system was constructed at the Site in late 2008 (TPG, 2014b).

The ERH system operated in 2009 and 2010 and extracted volatile vapors and liquids from the redwood gas holder. Over the duration of ERH, approximately 570 pounds of naphthalene and 5,900 pounds of benzene were recovered in the vapor phase. However, the most effective mechanism for mass removal during the ERH project was removal of coal tar from the redwood gas holder as the tar melted. Overall, approximately 557,000 pounds (55,700 gallons) of coal tar were extracted from the subsurface during ERH. The ERH remediation activities are documented in the *Redwood Gas Holder Closure Report* (TPG, 2014b).

1.5.5 Redwood Gas Holder Remediation – In Situ Soil Mixing

Due to the large volume of coal tar extracted during ERH operations, a large amount of consolidation was observed within the redwood gas holder with lesser amounts of settlement observed in the area immediately surrounding the redwood gas holder. During ERH treatment, the surface of the redwood gas holder subsided by as much as five feet. Geotechnical stabilization of the soils in this area was necessary to prevent further settlement of the ground surface prior to restoring the Site to its previous use as a parking lot.

A Workplan was prepared in January 2012 to implement ISSM to treat soil in the vicinity of the redwood gas holder (TPG, 2012a), which was approved by the RWQCB in a letter dated February 28, 2012 to Mr. Darrell Klingman of PG&E and Mr. Paul Louie of Upway Properties. The ISSM treatment was planned to provide geotechnical stability to soil in and around the redwood gas holder,

as well as provide additional containment of any remaining MGP residuals within the redwood gas holder.

ISSM was implemented in 2012 and 2013 using large diameter auger soil mixing and jet grouting. Following ISSM, an engineered cap was installed over the entire treatment area to further minimize the potential for settlement of the ground surface. Within the redwood gas holder, the upper zone to a depth of approximately 8.5 feet bgs was mixed using large diameter augers. Outside of the redwood gas holder, jet grouting was utilized to create a “ring” around the outside of the redwood gas holder from approximately 10 to 50 feet bgs to provide geotechnical support outside of the redwood gas holder and to provide additional containment for the residuals within the redwood gas holder and soils immediately underlying the gas holder. The jet grout columns outside of the redwood gas holder were spaced approximately three feet apart and approximately two feet outside of the redwood gas holder. Where possible, a second, outer ring of jet grout columns was placed outside, and overlapping, the inner ring, from a depth of approximately 15 to 50 feet bgs to provide additional geotechnical support and containment. Jet grouting was also conducted within the redwood gas holder from the base of the auger mixed zone to the base of the gas holder at approximately 22 feet bgs, with a minimum column spacing of 6.5 feet. The purpose of the jet grouting inside the redwood gas holder was to provide geotechnical support for the overlying auger mixed zone. The ISSM remediation activities are documented in the *Redwood Gas Holder Closure Report* (TPG, 2014b).

During remediation activities conducted at the redwood gas holder, a groundwater extraction and treatment (GWET) system was installed and operated to contain groundwater in the immediate vicinity of the redwood gas holder. The groundwater extraction system was turned off on May 27, 2014 in accordance with the RWQCB approved *GWET Shutdown Test Workplan* (TPG, 2014a).

1.5.6 Targeted Soil Excavation

In October 2011, targeted soil excavation and Site restoration activities were conducted to remove shallow soil with elevated lead concentrations in the area south of the entrance to the underground garage. The *Targeted Soil Excavation Workplan* (TPG, 2011d), and the *Addendum to the May 3 Targeted Soil Excavation Workplan* (TPG, 2011e), were approved by the RWQCB in a letter dated July 5, 2011 to Mr. Darrell Klingman of PG&E and Mr. Paul Louie of Upway Properties. The extent of the excavation is shown on Figure 5. The final depth of the excavation ranged from approximately 4.5 to 8 feet excluding the setback for the 12 kilovolt (kV) electric line running through the excavation area. Confirmation soil samples were collected from the bottom and the sidewalls of the excavation prior to backfilling. The excavated soil was transported off-site for disposal and clean, backfill material was imported to replace the contaminated soil. The backfill material was compacted in accordance with the City permit requirements and the surface was restored to pre-existing conditions as asphalt paving. The targeted soil excavation remediation activities are documented in the *Targeted Soil Excavation Completion Report* (TPG, 2012c).

1.5.7 Planter Area Remediation

Soil excavation activities were conducted during May and June, 2013 to remove impacted shallow soil in the planter areas in and around the parking areas at 111 Santa Rosa Avenue. The extent of the planter area excavations are shown on Figure 5. The work was conducted in general accordance with the *Planter Area Soil Excavation Workplan* (TPG, 2012b), which was approved by the RWQCB in a letter dated January 24, 2013 to Mr. Darrell Klingman of PG&E and Mr. Paul Louie of Upway Properties.

Soil within the planter areas was excavated to a depth of two feet unless tree roots or other subsurface obstacles prevented reaching this depth. In several areas, soil was excavated deeper than two feet to remove additional soil where elevated lead concentrations were observed.

Once the final depth was reached in each planter location, confirmation soil samples were collected in accordance with the approved Workplan, the excavation was lined with geotextile fabric, and the excavation was immediately backfilled with clean imported topsoil material. Excavated soil was transported off-site for disposal at an appropriately licensed disposal facility. The planter area remediation activities are documented in the *Planter Area Soil Excavation Completion Report* (TPG, 2013b).

1.5.8 Post-Remediation Site Restoration

Following completion of the remediation activities conducted through 2013, the parking lot at the Site was restored to pre-remediation conditions. This work included relocating the driveway entrance to its original location, relocating and/or removing utilities at the Site, reconstructing sidewalks, curbs, gutters, and parking areas, paving the western half of the parking lot, slurry coating and striping the entire parking lot, and installing new irrigation and landscaping in the planter areas. The restoration activities are documented in the *Redwood Gas Holder Closure Report* (TPG, 2014b).

2.0 NATURE AND EXTENT OF IMPACTS

The chemicals typically associated with former MGP sites include polycyclic aromatic hydrocarbons (PAHs), total petroleum hydrocarbons (TPH), benzene, toluene, ethylbenzene, and xylenes (BTEX), and select trace metals. The following discussions regarding the current nature and extent of impacts are based on the historical data collected since 1986. Where remediation activities have removed or treated historical soil sample locations, these samples have not been included in this evaluation because they are no longer representative of current Site conditions.

2.1 SOIL IMPACTS

All published analytical soil data has been summarized in a comprehensive Site database. The soil data used to evaluate the current nature and extent of impacts in the vicinity of the Site are summarized in Tables 1 through 4.

Soil data were divided into three main depth intervals for evaluation purposes:

- Samples collected from depths less than 5 feet bgs;
- Samples collected from depths of 5 feet bgs or greater, but less than 10 feet bgs; and,
- Samples collected from depths of 10 feet bgs or greater.

For cases where multiple samples from a boring were collected, the maximum concentration within each of the soil depth intervals was selected for display in the figures.

2.1.1 PAH Concentrations in Soil

In order to evaluate the extent of impact of PAHs at various depths, PAH concentrations were converted into carcinogenic PAH concentrations expressed in benzo(a)pyrene [B(a)P] equivalent concentrations. The B(a)P equivalent concentrations were calculated and expressed using the potency equivalency factors shown in the table below.

Factors to Calculate Carcinogenic PAH expressed in Benzo(a)Pyrene Equivalent Concentration	
Compound	Potency Equivalency Factor^(a)
Benzo(a)pyrene	1.0
Benzo(a)anthracene	0.1
Benzo(b)fluoranthene	0.1

Factors to Calculate Carcinogenic PAH expressed in Benzo(a)Pyrene Equivalent Concentration	
Benzo(k)fluoranthene	0.1
Chrysene	0.01
Dibenzo(a,h)anthracene	0.34
Indeno(1,2,3-c,d)pyrene	0.1

^(a) State of California Environmental Protection Agency (Cal/EPA), 1994 Appendix 1

PAH concentrations in soil at depths less than 5 feet bgs

Figure 6 shows the distribution of B(a)P equivalent concentrations at depths less than 5 feet bgs. The highest concentrations of B(a)P equivalent observed within this depth interval were generally observed scattered across the parking lot area of the on-site property (Figure 6).

PAH concentrations at depths greater than 5 feet bgs, but less than 10 feet bgs

Figure 7 shows the distribution of B(a)P equivalent concentrations at depths 5 feet bgs or greater, but less than 10 feet bgs. The highest concentrations of B(a)P equivalent observed within this depth interval were generally observed on the southern portion of the on-site property with some impacts also occurring the west of the Site along the PMG (Figure 7).

PAH concentrations at depths of 10 feet bgs or greater

Figures 8 shows the distribution of B(a)P equivalent concentrations at depths of 10 feet bgs or greater. The highest concentrations of B(a)P equivalent observed within this depth interval were observed within the footprint of the former redwood gas holder, on the southern portion of the on-site property, and to the west of the Site along the PMG (Figure 8).

2.1.2 Naphthalene Concentrations in Soil

Naphthalene concentrations at depths less than 5 feet bgs

Figure 9 shows the distribution of naphthalene concentrations at depths less than 5 feet bgs. The highest concentrations of naphthalene observed within this depth interval were generally observed scattered across the parking lot area of the on-site property.

Naphthalene concentrations at depths greater than 5 feet bgs, but less than 10 feet bgs

Figure 10 shows the distribution of naphthalene concentrations at depths 5 feet bgs or greater, but less than 10 feet bgs. The highest concentrations of naphthalene observed within this depth interval

were in the on-site parking lot, on the PMG along the southern border of the on-site property, and on the PMG to the west of the property.

Naphthalene concentrations at depths of 10 feet bgs or greater

Figure 11 shows the distribution of naphthalene concentrations at depths of 10 feet bgs or greater. The highest naphthalene concentrations observed within this depth interval were generally observed within the footprint of the former redwood gas holder, along the southern border of the on-site property, and to the west of the Site along the PMG.

2.1.3 TPH and BTEX Concentrations in Soil

Recent and historical TPH data has been compiled and categorized into the three standard TPH carbon ranges, quantified as gasoline (TPHg), diesel (TPHd), and motor oil (TPHmo). While the majority of the historical data for the Site falls into one of these three categories, some of the TPH data historically acquired has been quantified against other miscellaneous standards. In order to present this miscellaneous TPH data, it has been grouped into the standard TPH range which it most closely represents (Table 2).

TPH and BTEX at depths less than 5 feet bgs

Figures 12, 13, and 14 show the distribution of TPHg, TPHd/TPHmo, and BTEX, respectively at depths less than 5 feet bgs. TPHg concentrations in soil are generally low across the investigation area within this depth interval (Figure 12). TPHd/TPHmo impacts in soil within this depth interval are most prevalent on-site with the highest concentrations observed in the northeast and southwest portions of the Site (Figure 13). BTEX compounds were generally not detected within this depth interval with some low concentrations primarily along the south and west boundaries of the Site (Figure 14).

TPH and BTEX at depths 5 feet bgs or greater, but less than 10 feet bgs

Figures 15, 16, and 17 show the distribution of TPHg, TPHd/TPHmo, and BTEX, respectively at depths 5 feet bgs or greater, but less than 10 feet bgs. TPHg concentrations in soil were generally not detected across the investigation area within this depth interval (Figure 15). TPHd/TPHmo impacts in soil within this depth interval are most prevalent on-site with the highest concentrations observed in the southern portions of the Site (Figure 16). BTEX compounds were generally not detected in soil within this depth interval with low concentrations reported in only four on-site samples, primarily along the southern boundary of the Site (Figure 17).

TPH and BTEX at depths of 10 feet bgs or greater

Figures 18, 19, and 20 show the distribution of TPHg, TPHd/TPHmo, and BTEX, respectively at depths of 10 feet bgs or greater. The highest concentrations of TPHg in soil within this depth interval were observed in the former redwood gas holder (Figure 18). The highest concentrations of TPHd/TPHmo within this depth interval were observed in the former redwood gas holder, along the

southern portion of the Site, and extending to the neighboring property to the west of the Site (Figure 19). The highest concentrations of BTEX compounds within this depth interval were observed within the former redwood gas holder (Figure 20).

2.1.4 Lead Concentrations in Soil

Figures 21 through 23 show the concentration of lead in soil for each of the three depth intervals, respectively. Elevated concentrations of lead in soil at depths less than 5 feet bgs are generally scattered across the Site with some elevated detections to the west of the Site on the neighboring property and the PMG (Figure 21). The highest concentrations of lead within the depth interval from 5 feet bgs or greater, but less than 10 feet bgs occur in the southern portion of the Site and along the PMG to the east and west of the Site (Figure 22). In soil greater than 10 feet bgs, the highest concentrations of lead occur along the southern boundary of the Site and along the PMG to the east and west of the Site (Figure 23).

2.1.5 Arsenic Concentrations in Soil

Figures 24 through 26 show the distribution of arsenic in soil for each of the three depth intervals, respectively. Elevated concentrations of arsenic in soil at depths less than 5 feet bgs are scattered across the site with the highest concentrations along the western boundary of the Site within the planter area adjoining the two properties (Figure 24). At depths 5 feet bgs or greater, but less than 10 feet bgs, elevated concentrations of arsenic were observed at one location adjacent to the existing UST at the Site (Figure 25). In soil greater than 10 feet bgs, arsenic concentrations were generally low with the exception of one elevated detection along the PMG to the west of the Site (Figure 26).

2.2 GROUNDWATER IMPACTS

As discussed previously, groundwater monitoring was initially conducted sporadically following installation of the first wells at the Site in 1987. Since 1997, groundwater has been monitored twice yearly, with the exception of 2006 when only one groundwater monitoring event was conducted.

The most recent published semiannual groundwater monitoring results are from September 2014 (TPG, 2015b). Groundwater water elevations from this sampling event are shown in Figure 3. The groundwater analytical results from this sampling event are summarized in Figure 27 (TPG, 2015b). Historical data tables for the previous groundwater monitoring events described above are included in Appendix A and show the historical variations in groundwater concentrations. The results from the September, 2014 sampling event are summarized below.

2.2.1 PAHs

PAHs were only detected in one monitoring well during September 2014 groundwater sampling event. Fluoranthene and pyrene were detected in monitoring well MW-2 at concentrations of 0.16 and 0.19 micrograms per liter ($\mu\text{g/L}$), respectively. PAHs were not detected in any of the other monitoring wells during this sampling event.

2.2.2 TPH and BTEX

TPH_g was not detected in monitoring wells during the September 2014 sampling event.

TPH_d was detected in monitoring wells MW-2, MW-9, and MW-21 at concentrations of 53, 57, and 510 µg/L, respectively. TPH_{mo} was detected in monitoring wells MW-2, MW-9, and MW-21 at concentrations of 150, 130, and 670 µg/L, respectively.

BTEX compounds were not detected in monitoring wells during the September 2014 sampling event.

2.2.3 Distribution of NAPL

Petroleum NAPL has been historically observed in several borings. Figure 28 shows boring and/or well locations where NAPL has been observed in soil. NAPL observed in soil generally consists of residual phase NAPL trapped between the grains of soil or within fractures in clay at or near the water table. Although NAPL has been observed in soil at several locations across the Site, it has only been observed floating on the water table in two wells, MW-14 and PM-1.

Groundwater data collected from the Site indicates that current groundwater impacts are limited to areas where residual MGP impacts, such as NAPL, are known to be present and there is no indication that Site contaminants are migrating to the creek. The mobility of NAPL typically decreases over time due to a variety of naturally occurring processes. At this Site, these processes have been occurring for many decades since the NAPL release likely occurred approximately 100 years ago. Observations and data collected from the Site indicate that the NAPL has very limited mobility, consistent with the suspected age of the release. A general discussion of the NAPL mobility is presented in the following sections.

2.2.3.1 Mobility of NAPL

Several factors govern the mobility of NAPL in the subsurface including the properties of the NAPL such as density, viscosity, and interfacial tension, in addition to properties related to subsurface conditions such as hydraulic conductivity, NAPL saturation, and the hydraulic gradient. Data have been collected from the Site to evaluate the potential mobility of the NAPL under existing site conditions.

As a NAPL body migrates through the subsurface, a significant portion of the NAPL is retained in the porous media trailing the NAPL body, thereby depleting and eventually exhausting the mobile NAPL body (Cohen and Mercer, 1993). Below the water table, residual saturation of NAPL is the saturation at which NAPL is immobilized (trapped) by capillary forces as discontinuous ganglia under ambient groundwater flow conditions (Cohen and Mercer, 1993). As a result, a NAPL body that does not have an infinite supply of NAPL can only migrate a limited distance before the saturation of NAPL is reduced to its residual saturation and it is no longer mobile. For reference, published values of residual saturation for crude oil in sandstone, or petroleum reservoirs, ranges from approximately 16 to 50 percent (Cohen and Mercer, 1993).

The mobility of the NAPL in the groundwater zone is largely a function of the saturation of the NAPL in the porous media where the residual saturation of the NAPL defines the point at which the NAPL is no longer able to move under ambient conditions. When more than one fluid exists in a porous medium, the fluids compete for pore space. The result is that the mobility of each of the fluids is reduced (Cohen and Mercer, 1993). If one fluid has a high saturation, then a higher percentage of the pore space is available for that liquid to flow through. Conversely, the lower the saturation of a particular fluid, the less pore space is available for the fluid to flow through. In general, the mobility of NAPL in the groundwater zone decreases exponentially as the saturation of NAPL decreases.

Although the exact source of the NAPL is not known, if the source were related to MGP operations previously conducted at the Site, then the NAPL would be on the order of 100 years old. The fact that the NAPL is still present after decades, demonstrates the limited mobility of the NAPL. Additionally, the NAPL is likely less mobile now than it was when it was released since moving through the subsurface causes a trail of residual NAPL to remain behind the NAPL body, thus reducing the saturation of the NAPL and reducing the NAPL mobility as discussed previously. Over time, the NAPL is also subject to a number of naturally occurring processes which tend to preferentially remove the lighter fractions in the NAPL. As a result, the heavier, less mobile fraction of the NAPL remains in the subsurface and is less mobile than the original source.

Mobility testing conducted on representative cores from NAPL-impacted areas of the Site indicated that the NAPL saturation at these locations was below residual levels indicating that the NAPL is essentially immobile under current Site conditions at these locations. These results are consistent with the observed distribution of NAPL in the subsurface and the suspected age of the NAPL release.

2.2.3.2 *Physical Properties Testing Program*

To better understand the physical properties that control the mobility and potential recoverability of NAPL, soil and NAPL samples, were collected from within the impacted zone and subjected to various physical tests to evaluate NAPL mobility (ENV, 2005b). Results of the testing are discussed in the following sections.

2.2.3.3 *Fluid Properties Testing*

During drilling in monitor well MW-16, a sample of the NAPL (MW-16-21.5-23) was collected from the outside surface of the split spoon sampler for fluid properties testing. Only limited volumes of NAPL were available which limited the types of analyses the laboratory could perform on the sample. Analyses that were performed include density and viscosity.

The density of the NAPL was measured at 0.9410 grams per cubic centimeter (g/cc) at 70 degrees Fahrenheit. For comparison, the density of water is 1 g/cc at 39.2 degrees Fahrenheit and therefore the NAPL can be considered a light non-aqueous phase liquid since it is less dense than water. This result is consistent with visual observations in the field. The viscosity of the NAPL was also measured at 70 degrees Fahrenheit and was found to be 561 centipoises. For comparison purposes, the viscosity of water is 0.89 centipoises at 77 degrees Fahrenheit, and the viscosity of maple syrup is approximately 150 centipoises. These data indicate that the NAPL is highly viscous which is consistent with field observations.

An additional test was attempted to measure the interfacial tension of the NAPL. Because only a small volume of NAPL from the site was available, the lab was not able to perform this analysis. However, because one of the mobility tests described in the following subsections required a larger volume of NAPL than was available from the site, the laboratory prepared a blend of site NAPL with a NAPL of similar properties to perform the mobility test. The interfacial tension of this NAPL blend was measured at 72 degrees Fahrenheit and found to be 31 dynes per centimeter for the NAPL air phase pair and 22.3 dynes per centimeter for the NAPL water phase pair (ENV America, 2005b).

2.2.3.4 *NAPL Mobility Testing*

Intact core samples from three borings drilled during the 2005 groundwater investigation were sent to PTS Laboratories for NAPL mobility testing (ENV, 2005b). The samples were selected from the depth interval in each boring which had the greatest visible amount of NAPL present and therefore likely represent the depth ranges where NAPL is most mobile at each of these boring locations.

The first test was a free product mobility test that was conducted by taking the intact core samples and spinning them in a centrifuge to subject them to a force of 1,000 times that of gravity for one hour. The volume of fluids drained from the core was measured and the water and NAPL fluid saturations in the sample were recorded before and after centrifuging the sample. The testing indicated that NAPL could not be liberated from the soil even when centrifuging the sample under extreme conditions.

The second test performed evaluated the NAPL saturation capacity of the samples. This test involved taking the drained cores from the previous test and resaturating them with NAPL and then subjecting them to the previous test to drain the samples. This test was performed to evaluate the residual saturation by starting with a NAPL saturated sample since the initial NAPL saturations measured in the previous test may be below residual levels. The results indicate the residual saturation of all samples after resaturating and centrifuging was slightly higher in all samples than the NAPL saturation observed in the original samples indicating that the NAPL in the original field samples was below the residual NAPL saturation. Under these conditions, the NAPL would be essentially immobile.

3.0 SCREENING-LEVEL HUMAN HEALTH RISK ASSESSMENT

A *Screening-Level Human Health Risk Assessment* (SLHHRA) was prepared by Iris Environmental for the Site and is presented in Appendix B. The primary purpose of the SLHHRA was to determine whether levels of chemicals present in soil could pose a risk to human health based on current and potential future property uses. The results of the SLHHRA have been used to identify areas of the Site where remedial/mitigation measures and/or risk management may be appropriate, with the overall goal of long-term protection of human health.

Soil data considered relevant for a SLHHRA that includes future land use scenarios typically include all data for soil samples from depths up to and including 10 feet bgs; 10 feet is considered a typical maximum depth for excavation activities associated with subsurface maintenance/ landscaping work or site redevelopment.

For the purposes of supporting risk management decisions, three data subsets were prepared and evaluated in the SLHHRA, including the on-site property (111 Santa Rosa Avenue; APNs 010068020 and 010068021), the 438 First Street Property (APN 010068019), and off-site public Right of Way (ROW) areas consisting of all other areas adjacent to the Site (Figure 2).

3.1 IDENTIFICATION OF CHEMICALS OF POTENTIAL CONCERN

Chemical compounds included in the SLHHRA are those constituents detected above laboratory reporting limits in at least one soil sample. Although Cal/EPA and USEPA guidance allow for the elimination of inorganic constituents (i.e., metals) from the quantitative risk assessment if they are detected at levels within local background/ambient concentrations, all chemicals detected in on-site and off-site soil samples have been conservatively included in the quantitative SLHHRA. The COPCs detected in on-site and off-site soil that are included in the quantitative SLHHRA include 13 volatile organic compounds (VOCs), TPH, total polychlorinated biphenyls (PCBs), 17 PAHs, and 19 inorganics (Appendix B).

3.2 EXPOSURE ASSESSMENT

To determine whether the chemicals present pose a risk to human populations under current and future anticipated conditions, populations that may potentially be exposed and the pathways through which exposures may occur were identified. The conceptual Site Model (CSM) for the Site is shown in Figure 4 of the SLHHRA (Appendix B) and illustrates the relationship between the chemical sources, exposure pathways and potential receptors. These source-pathway-receptor relationships provide the basis for the quantitative exposure assessment. Only the complete pathways were evaluated in the SLHHRA. Based on the current and assumed hypothetical future uses of the on-site Property, the populations included in the SLHHRA consist of the following:

- Current on-site worker (also evaluated as protective of infrequent visitors);
- Hypothetical future on-site commercial worker (including short-term construction/intrusive workers); and,

- Hypothetical future on-site resident.

Similar to the on-site Property, the off-site 438 First Street Property and off-site public ROW areas are evaluated under hypothetical future commercial worker and residential scenarios, to provide the basis for any mitigation measures and/or deed restrictions, if warranted, for these areas.

Under current conditions, the potential pathways through which commercial workers could be exposed to COPCs in soil are considered incomplete or insignificant. For the purposes of supporting risk management decisions, this SLHHRA assumes that hypothetical future receptors (on-site commercial workers and residents) could be exposed to COPCs in soil via incidental ingestion, dermal contact, and inhalation of COPCs volatilized or re-suspended as respirable particulates in outdoor air.

3.3 COMPARISON OF EXPOSURE POINT CONCENTRATIONS (EPCs) TO RISK-BASED AND AMBIENT BASED SCREENING CONCENTRATIONS

Exposure point concentrations (EPCs) are the representative chemical concentrations that a receptor may contact at an exposure area over the exposure period. The EPC approach is based on the concept that individuals contact the impacted medium on a periodic and random basis. Because of the repeated and random nature of such contact, human exposure does not occur at a fixed point, but rather at a variety of points with equal likelihood that any given point within the exposure area will be the contact location on any given day. Thus, the EPC is based on an average chemical concentration within the exposure area. The calculation of EPCs for each COPC dataset includes an initial evaluation of the distribution of the data as a predecessor step to employing the best statistical methodology for determining a concentration that estimates the mean of the dataset with a prescribed level of confidence.

For the purposes of supporting risk management decisions, potential human health risks for the future hypothetical receptors (on-site commercial and residential populations) are evaluated using risk-based screening concentrations (RBSCs) and ambient based screening concentrations (ABSCs) protective of the exposure pathways identified as potentially complete for these receptors. A detailed discussion of how the RBSCs and ABSCs were developed is included in Appendix B. A comparison of RBSCs and ABSCs to EPCs for COPCs in soil is used to determine whether levels of chemicals detected in soil at the on-site Property, off-site 438 First Street Property, and off-site public ROW could pose a risk to human health above acceptable risk and hazard levels based on potential future property uses. The results of the comparison are used to support the mitigation measures and deed restrictions proposed in this RAP.

The selection of commercial land use RBSCs for the hypothetical future commercial worker, and the residential land use RBSCs selected for the hypothetical future resident for the COPCs in on-site Property soil (0-10 feet bgs), off-site 438 First Street Property soil (0-10 feet bgs), and off-site public ROW soil (0-10 feet bgs), are discussed in detail in the SLHHRA and presented in Tables 2a through 2c, respectively in Appendix B.

Given that risk-based residential cleanup goals for carcinogenic PAHs (CPAHs) and arsenic in soil are below ambient concentrations, the numerical remedial goal for these compounds would not be risk-

based, but rather would be based on the ambient concentrations of these compounds. ABSCs for CPAHs and arsenic in on-site Property soil (0-10 feet bgs), off-site 438 First Street Property soil (0-10 feet bgs), and off-site public ROW soil (0-10 feet bgs) are discussed in detail in the SLHHRA and presented in Tables 2a through 2c, respectively in Appendix B.

A comparison of RBSCs and ABSCs to EPCs for COPCs in soil has been used to determine whether levels of chemicals detected in soil at the on-site Property, off-site 438 First Street Property, and off-site public ROW could pose a risk to human health above acceptable risk and hazard levels based on potential future property uses. The results of the comparison of soil RBSCs and ABSCs to soil EPCs are discussed below.

3.3.1 Current Land Use

Under current Site conditions, the potential pathways through which on-site commercial workers could be exposed to COPCs in soil are considered incomplete or insignificant. Therefore, the current Site conditions are fully protective of the health of current on-site commercial populations and no further remedial or mitigation measures are warranted. Risk management measures, such as a cap maintenance/soil management plan and deed restrictions, are warranted to ensure that the Site continues to remain protective of human health.

3.3.2 Potential Future Land Uses

For the purposes of supporting risk management decisions, a comparison of RBSCs and ABSCs to EPCs for COPCs in soil is used to evaluate potential human health risks under potential future land use scenarios. The following are the conclusions and recommendations for the on-site Property, off-site 438 First Street Property, and off-site public ROW under hypothetical future commercial and residential land use scenarios.

3.3.2.1 *On-site Property*

The results of the comparison of EPCs for COPCs in on-site Property soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicates that levels of arsenic, benzene, CPAHs, naphthalene, TPHd, and lead are above levels suitable for future commercial land use if the Site were to be redeveloped for other commercial uses (e.g., if the existing cover were to be removed, and/or if a building were to be constructed elsewhere on-site). Accordingly, risk management measures, such as a cap maintenance/soil management plan and a deed restriction, are warranted for the protection of future commercial populations (including short-term construction/intrusive workers) at the on-site Property.

The results of the comparison of EPCs for COPCs in on-site Property soil (0-10 feet bgs) to residential soil RBSCs and ABSCs indicates that levels of arsenic, benzene, CPAHs, ethylbenzene, naphthalene, TPHd, total PCBs, and lead are above acceptable levels suitable for future residential land use if the Site were to be redeveloped for residential use. Accordingly, risk management measures that restrict the future residential use of the property are warranted.

3.3.2.2 *Off-site 438 First Street Property*

The comparison of EPCs for COPCs in off-site 438 First Street Property soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicates that levels of arsenic and lead at depths greater than 2 feet bgs in the small landscaped planter areas along the eastern boundaries of the property are above levels suitable for future commercial land use if this property were to be redeveloped for other commercial use. Accordingly, risk management measures such as a cap maintenance/soil management plan for soil below 2 feet bgs in the planter areas are warranted for the protection of future commercial populations at the off-site 438 First Street Property.

The comparison of EPCs for COPCs in off-site 438 First Street Property soil (0- 10 feet bgs) to residential soil RBSCs and ABSCs indicates that levels of arsenic and lead at depths greater than 2 feet bgs in the small landscaped planter areas along the eastern boundaries of the property are above levels suitable for future residential land use if the Site were to be redeveloped for residential use. Accordingly, risk management measures that restrict the future residential use of the property are warranted.

3.3.2.3 *Off-site Public ROW*

The comparison of EPCs for COPCs in off-site public ROW soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicates that levels of CPAHs and naphthalene are above levels suitable for future commercial land use (e.g., if the existing cover in the off-site public ROW, specifically along the PMG, were to be removed). Accordingly, risk management measures are warranted to ensure that impacts that remain in the PMG are properly managed.

The comparison of EPCs for COPCs in off-site public ROW soil (0-10 feet bgs) to residential soil RBSCs and ABSCs indicates that levels of CPAHs, naphthalene, and lead along the PMG are above levels suitable for future residential land use. Accordingly, risk management measures are warranted to ensure that impacts that remain in the PMG are properly managed.

4.0 SUMMARY OF FEASIBILITY STUDIES

In June 2006, a *Corrective Action Plan* (CAP) was prepared for the Site (TPG, 2006a). The CAP included an assessment of on-site and off-site impacts to soil and groundwater. The CAP also contained a Feasibility Study (2006 FS) that evaluated remedial alternatives for impacted soil and groundwater. The groundwater portion of the 2006 FS was preliminary in nature because the scope and scale of the selected groundwater remedial alternative would ultimately be dependent on the nature and extent of residual soil impacts following implementation of the selected soil remedy. The 2006 FS stated that following implementation of the selected soil remedy, groundwater alternatives would be re-evaluated and an appropriate final groundwater remedy selection would be made, consistent with the remedial action goals established for the Site.

Following completion of the CAP, additional investigations were conducted to further evaluate potential sources at the Site. During these investigations, elevated concentrations of benzene and naphthalene were observed within the footprint of the redwood gas holder. Based on the evaluation of investigation results for soils in the redwood gas holder, it was determined that conventional excavation approaches could result in the unacceptable emission of elevated concentrations of volatile compounds into the atmosphere. Accordingly, a Redwood Tank FS was prepared to identify a remediation alternative that could be implemented in a manner protective of human health and the environment (TPG, 2007c). Remedial measures were subsequently implemented as discussed in Section 1.5, and the *Redwood Gas Holder Closure Report* was submitted in April 2014 (TPG, 2014b).

In 2010, the *Draft Supplemental Feasibility Study* was completed for the Site to fulfill the requirements set forth in Cleanup and Abatement Order (CAO) No. R1-2006-0033, revised by the RWQCB on March 27, 2006. This *Supplemental Feasibility Study* (Supplemental FS) was finalized with RWQCB comments in 2012 (TPG, 2012d). The Supplemental FS evaluated soil and groundwater remedial alternatives for the Site based on the remedial measures taken and the additional information collected since the 2006 FS was completed. The remedial alternatives selected in the Supplemental FS for soil and groundwater were determined to be appropriate to achieve the remedial action goals established for the Site. These remedial action goals are: 1) to ensure that concentrations of chemicals remaining in soil and groundwater at the Site are protective of human health and the environment to the extent practicable, and 2) to protect and restore the current and potential beneficial uses of ground and surface water to the extent feasible and practicable.

The Supplemental FS evaluated four soil and four groundwater remediation alternatives (including the No Action alternatives) that were developed by combining compatible and complimentary options into remedial action scenarios that would address the soil and groundwater contamination. The remedial alternatives evaluated for soil were:

- Soil Alternative No. 1: No Action
- Soil Alternative No. 2: Cap and Deed Restriction
- Soil Alternative No. 3: Targeted Soil Excavation (including UST removal)
- Soil Alternative No. 4: Site Wide Soil Excavation (including UST removal)

Ultimately, a combination of Alternative 2, Cap and Deed restriction, and Alternative 3, Targeted Soil Excavation, was selected as the most appropriate soil remedial alternative. Figure 29 shows the targeted soil excavation areas in the selected soil remedial alternative.

Since the Supplemental FS was completed in 2010, many of the elements outlined in the selected remedy for soil have been implemented. Remediation of the shallow impacted soils immediately south of the underground parking entrance was completed in October, 2011 (TPG, 2012c). Remediation of the redwood gas holder, excavation of shallow soil in planter areas, and Site restoration activities were completed in 2013 (TPG 2013b; 2014b). Site restoration activities included re-locating the driveway entrance to its pre-remediation location, reconstructing damaged curbs and sidewalks, repaving and/or slurry coating the parking lot, and replacing the landscaping in the planter areas. Currently the Site is capped and groundwater is not being used as a water supply. Removal of the existing steel UST, as well as targeted soil excavation beneath the existing UST and the two USTs formally located in front of the building entrance (removed in June 2006), have been placed on hold pending land use circumstances that will allow for additional significant disruption. The location of these two areas is shown on Figure 30.

The implemented elements of the soil remedy approved in the Supplemental FS have reduced the potential for future mobilization of Site contaminants. As requested by the RWQCB (letter dated April 25, 2014), and to address these changed conditions, a *Groundwater Feasibility Study* (Groundwater FS) (TPG, 2015), was submitted and subsequently approved on March 13, 2015 by the RWQCB. The Groundwater FS evaluated four alternatives for groundwater that would be implemented in conjunction with the completed and remaining elements of the previously selected soil remedy to provide an overall remedy for the Site. The four groundwater alternatives evaluated were:

- Groundwater Alternative No. 1: No Action
- Groundwater Alternative No. 2: Long-term Groundwater Monitoring
- Groundwater Alternative No. 3: Grout or Slurry Barrier
- Groundwater Alternative No. 4: Funnel and Gate

While the results of the comparison of alternatives indicated that Alternatives 2, 3, and 4 would satisfy the remedial action goals, Alternative 2 (Long-term Groundwater Monitoring) presents significantly less impacts to the creek, the PMG, and the surrounding community. Construction of Alternative 3 would require construction within the creek resulting in significant impacts to the creek, the PMG, and the surrounding community. Alternative 4 would require even more construction in the creek and also require construction activities on the 438 First Street Property. Because Alternative 2 satisfies the remedial action goals and could be implemented with significantly less impact to the creek, the PMG, and the surrounding community, Alternative 2 was selected as the preferred groundwater Alternative.

The overall proposed soil and groundwater remedy selected for the Site includes the following components:

- Removal of the former USTs in the parking lot west of the building entrance (completed in June 2006);

- Remediation of the redwood gas holder (completed in 2013);
- Removal of the existing on-site UST (on hold pending land use changes);
- Targeted excavations to remove heavily impacted soils in the vicinity of the former and existing USTs (on hold pending land use changes), and shallow soils in the area south of the underground driveway entrance (completed in 2011);
- Long-term groundwater monitoring;
- Maintaining current cap; and,
- Deed restrictions.

5.0 OPERATIONS AND MAINTENANCE PLAN

An Operations and Maintenance Plan (O&M Plan) for post-remediation groundwater monitoring and cap inspection and maintenance activities will be prepared for each property and implemented as part of the post-remediation monitoring program. In addition to groundwater monitoring and cap inspection and maintenance activities, the O&M Plan will also include the details of the five-year reviews that will be conducted.

An Operations and Maintenance Agreement for groundwater monitoring will be signed and executed between the RWQCB and PG&E to ensure the implementation of the semiannual monitoring activities described in the O&M Plan. Separate Operations and Maintenance Agreements will be signed and executed between the RWQCB and the current owners of each property to ensure the implementation of the annual cap inspection, access by PG&E for groundwater monitoring activities, and associated reporting activities described in the O&M Plan.

5.1 GROUNDWATER MONITORING PROGRAM

Groundwater monitoring is proposed at 14 monitoring well locations (monitoring wells MW-7, MW-9, MW-10, MW-12 and MW-16, MW-17, MW-19S, MW-19D, MW-20, MW-21, MW-22, MW-23, EBAMW-1, and EBAMW-2) as shown on Figure 31. These wells constitute a subset of existing wells and were selected to provide a good spatial distribution of groundwater sample locations including the most downgradient wells. These wells are generally screened within a hydrogeologic unit where off-site migration of shallow impacted groundwater, or migration of contaminants to Santa Rosa Creek, would most likely occur. The monitoring data will be used to verify that groundwater conditions are stable. If the monitoring results indicate that groundwater conditions are changing and no longer stable, additional monitoring, investigation, or other remedial actions would be implemented as appropriate.

During the first five years, groundwater monitoring events will occur in the spring and fall to coincide with expected high and low groundwater levels. As discussed further in Section 5.3, after the first five years, a comprehensive groundwater evaluation report will be prepared and submitted to the RWQCB.

Groundwater monitoring activities will be conducted in accordance with the procedures developed in a Groundwater Monitoring Workplan, which will be prepared as a separate document. In general, the groundwater monitoring program will include the following:

- Static water level measurements;
- Low-flow purging and sampling;
- Analytical laboratory testing; and
- Reporting.

Groundwater samples from each well, and one duplicate sample, will be analyzed for: TPHd and TPHmo using USEPA Method 8015B with silica gel cleanup; TPHg and benzene using USEPA Method 8260B; and PAHs using USEPA Method 8270 SIM. One trip blank sample will also be analyzed for TPHg and BTEX.

5.1.1 Reporting

Semiannual groundwater monitoring reports will be prepared summarizing the results of each groundwater monitoring event.

5.2 CAP OPERATIONS AND MAINTENANCE

An O&M Plan will be prepared for each property and implemented as part of the post-remediation monitoring plan. Site O&M activities will consist of routine inspections and documentation to show that the capped surfaces in restricted areas remain in good condition, and land uses are compliant with the property usage restrictions.

The O&M Plans will consist of an annual Site inspection which will include:

- Visual inspection of all capped surfaces in restricted areas;
- Notation of significant cracks or degradation in the concrete, AC, or other Site covers in restricted areas;
- Appropriate cap repair and replacement in restricted areas; and,
- Inspection of water drainage patterns and potential erosion issues.

The annual inspection will be documented in a report for each property, which will also include notations of any Site modifications to the cap that were made during the previous year or observed soil erosion issues.

In addition to cap inspections and reporting, the O&M Plans will present the details of post-remediation groundwater monitoring discussed in Section 5.1. An Operation and Maintenance Agreement will also be entered into between RWQCB and each property owner to ensure the implementation of the O&M Plan.

5.3 FIVE-YEAR REVIEW

Reviews will be conducted every five years following the RWQCB approval of the proposed O&M Plan. The review will include a Site inspection, technical assessments of the ongoing monitoring, presentation of opportunities for optimization of the post-remediation program, any changes to conditions and land use or standards, and any updated risk calculations and assessments, where relevant.

In addition, PG&E will also continue to search for a suitable method to remove the existing steel UST and its contents without causing a nuisance condition for the building tenants or the community. Removal of the existing steel UST, as well as targeted soil excavation beneath the existing UST and the two former USTs located in front of the building entrance (removed in June 2006), have been placed on hold pending land use circumstances that will allow for additional significant land use disruption. The five-year review will include information on any new technologies and/or methodologies that may be suitable for effectively completing this work. The results of the five-year

reviews will be presented in written reports together with recommendations and follow-up actions, if any.

6.0 LAND USE COVENANTS

Issuance of a Land Use Covenant (LUC) is an appropriate response action to protect against the future release or threatened release of materials and/or wastes. LUCs will be pursued for the Site, the off-site 438 First Street Property, and off-site ROW, to ensure owners and any party that leases the property(ies) (current and future) are aware of areas where chemical residuals remain in soil or groundwater that may have an adverse health impact if disturbed without taking proper precautions.

Covenants to restrict property use, recorded in the form of LUCs, will disclose information about the properties' residual contamination to the local government and the public and will make current and future property owners responsible for following land use restrictions and protecting capped surfaces. LUCs will remain binding for current and subsequent property owners and in effect until they are terminated or modified by the RWQCB.

LUCs will prohibit future alteration of existing cover features such as concrete foundations, concrete or asphalt paving, and planter soils in areas with residual contamination above concentrations that allow for unrestricted land-use, unless adequately replaced.

The location of the restricted areas will be surveyed and a legal description included in the LUC. Areas lying outside the restricted areas will not require special protections unless unknown contamination is encountered. At a minimum, an LUC will include the following requirements:

- All uses and development of restricted areas will preserve the integrity and physical accessibility of the capped surfaces (including planters overlying impacted soils), and groundwater monitoring wells.
- Activities that will disturb impacted soil below the capped surfaces (including planter areas) will not be permitted without a Soil Management Plan approved by the RWQCB and an associated Health and Safety Plan (HASp).
- Any contaminated soil brought to the surface by grading, excavation, trenching or backfilling will be managed in accordance with applicable provisions of state and federal law and in accordance with the Soil Management Plan.
- Capped surfaces and groundwater monitoring wells will not be altered without RWQCB approval.
- Installation of wells and extraction of groundwater will not be allowed without RWQCB approval.

7.0 SUSTAINABLE PRACTICES

The development of future activities described in this report will be conducted in a sustainable manner. Sustainable practices corresponding to field activities that are least disruptive will be employed where feasible and practicable during the ongoing activities. To help facilitate identification and implementation of sustainable practices during these activities, a simple sustainability framework referred to as the Green Remediation Evaluation Matrix (GREM) was developed. The foundation of this framework is the three triple bottom line elements that are typically associated with sustainability: (1) environmental, (2) economic, and (3) social elements. Within each of the three sustainability elements, stressors which affect specific media are identified, as are the mechanisms for the effect on each medium. Correspondingly, a metric is identified to measure the effect on the stressor. Metrics used for each stressor vary based on the nature of the stressor. These metrics include estimates of the amount of CO₂ equivalents (for greenhouse gas emissions), PM-10 generation measured in milligrams per cubic meters (for airborne particulates), and other calculations and/or ratings that may be appropriate to define the stressor. Following identification of stressors and potential impacts from the proposed work, impact-reduction alternatives are identified (i.e., sustainable best management practices) for implementation during work activities to reduce the impact on the stressor. These impacts will be tracked and measured during the work using the metrics identified.

8.0 PUBLIC PARTICIPATION

The RAP will be subject to a 30-day public comment period to solicit community input on the adequacy of the RAP. The availability of the RAP for public comment will be advertised through a public notice in the Santa Rosa Press Democrat and the distribution of a fact sheet to nearby property owners and the key contact mailing list. At the mid-point of the public comment period, the RWQCB may host a public meeting to explain the RAP and solicit feedback, as warranted. At the close of the public comment period, the RWQCB will review and respond to all public comments prior to making a decision to approve, modify or deny the RAP.

9.0 CONCLUSIONS AND RECOMMENDATIONS

This RAP summarizes the historical investigations, feasibility studies, and remedial actions that have been completed. This RAP also presents the nature and extent of remaining impacts to soil and groundwater, and the results of a SLHHRA that was prepared to determine whether levels of chemicals remaining in soil at the Site and adjoining properties could pose a risk to human health based on current and potential future property uses. The results of the SLHHRA identified areas of the Site and adjoining properties where mitigation measures and/or risk management may be appropriate, with the overall goal of long-term protection of human health.

Under current conditions, the potential pathways through which commercial workers/site visitors could be exposed to COPCs in soil are considered incomplete or insignificant. Therefore, the current conditions are fully protective of the health of current commercial populations and no further remedial or mitigation measures are warranted. Risk management measures, such as a cap maintenance/soil management plan and deed restrictions are warranted to ensure that the Site and off-site areas continue to remain protective of human health.

Overall the soil and groundwater remedy includes the following components:

- Pre-development (1987-1988) soil excavations at three on-site locations (complete);
- Removal of impacted soil from the bed of the Santa Rosa Creek, and lining of the creek bed, conducted in conjunction with the PMG construction in 2004 (complete);
- Removal of the former USTs in the parking lot west of the building entrance (complete);
- Remediation of the redwood gas holder (complete);
- Removal of the existing on-site UST (on hold pending land use change);
- Targeted excavations to remove heavily impacted soils in the vicinity of the former and existing USTs (on hold pending land use change), and shallow soils in the area south of the underground driveway entrance (complete);
- Long-term groundwater monitoring;
- Maintaining cap on restricted areas; and,
- Deed restrictions.

The majority of these remediation components have been completed. However, removal of the existing steel UST, and targeted soil excavation beneath the existing UST and the two former USTs located in front of the building entrance, have been placed on hold pending land use circumstances that will allow for additional significant land use disruption. PG&E will continue to search for a suitable method to remove the existing steel UST and its contents without causing a nuisance condition for the building tenants or the community.

An O&M Plan for post-remediation groundwater monitoring and cap inspection and maintenance activities will be prepared and implemented as part of the post-remediation monitoring program. Groundwater monitoring is proposed at 14 monitoring well locations semiannually. Five-year reviews will be conducted following the RWQCB approval of the proposed O&M Plan. The reviews will

include an inspection of restricted areas, technical assessments of the ongoing monitoring, presentation of opportunities for optimization of the post-remediation program, any changes to conditions and land use or standards, and any updated risk calculations and assessments, where relevant. The reviews will also include information on any new technologies and/or methods that may be suitable for addressing the existing UST without causing a nuisance condition for the building tenants or the community.

LUCs will be pursued with all property owners with impacted soil/groundwater to ensure owners and those leasing the property(ies) (current and future) are aware of the restricted areas where chemical residuals remain in soil or groundwater that may have an adverse health impact if disturbed without taking proper precautions. The location of the restricted areas will be surveyed and a legal description prepared for each LUC. Areas lying outside the restricted areas will not require special procedures unless unknown contamination is encountered.

This RAP will be subject to a 30-day public comment period to solicit community input on the adequacy of the RAP. The RWQCB may host a public meeting to solicit feedback, as warranted. At the close of the public comment period, the RWQCB will review and respond to all public comments prior to making a decision to approve, modify or deny the RAP.

Notes:

* Sample depth is estimated

** Detection limit is unknown and assumed 0 for Benzo (a) Pyrene equivalent calculations

<# = not detected at or above value indicated

--- = not analyzed

Bold font indicates detections above the laboratory reporting limit

Benzo (a) Pyrene (eq) represent the sum of the concentration of each carcinogenic PAH multiplied by its toxicity equivalence factor (except for naphthalene)

PAH = polycyclic aromatic hydrocarbons

Notes:

- (1) Lab analyses was for TPH carbon chain C4-C12
- (2) Lab analyses was for TPH carbon chain C5-C12
- (3) Lab analyses was for TPH carbon chain C10-C24
- (4) Lab analyses was for TPH carbon chain C10-C28
- (5) Lab analyses was for TPH-extractable
- (6) Lab analyses was for Total Recoverable Petroleum Hydrocarbons (TRPH)
- (7) Lab analyses was for TPH carbon chain C19-C36
- (8) Lab analyses was for TPH carbon chain C24-C36
- (9) Lab analyses was for TPH-Heavy
- * Sample depth is estimated
- <# = not detected at or above value indicated
- = not analyzed
- Bold font indicates detections above the laboratory reporting limit
- TPH = Total Petroleum Hydrocarbons
- ND = not detected

Notes:

* Sample depth is estimated

<# = not detected at or above value indicated

--- = not analyzed

Bold font indicates detections above the laboratory reporting limit

BTEX = Benzene, Toluene, Ethylbenzene, Total Xylenes

ND = not detected

EXPLANATION

- EXISTING GROUNDWATER MONITORING WELL
- GAS HOLDER, PRESENT 1893;
35,000 cu ft CAPACITY (REDWOOD GAS HOLDER)
- 10,817 gal EXISTING UST
- BUILDING FOOTPRINT
- WELL NAME
- TOTAL PETROLEUM HYDROCARBON (TPH) DIESEL
- TPH-MOTOR OIL

Well Name	TPHd	TPHmo	Fluoranthene	Pyrene
MW-10	<49	<99	<0.11	<0.11

- NOTES:
1. NA INDICATES NOT ANALYZED.
 2. < INDICATES NOT DETECTED AT OR ABOVE LABORATORY DETECTION LIMIT SHOWN.
 3. ALL CONCENTRATIONS ARE IN MICROGRAMS PER LITER (µg/L)

Notes:

(1) sample was filtered by the laboratory prior to analysis using 0.7 micron glass fiber filter

(2) sample extract was subjected to silica gel treatment prior to analysis

TPH = total petroleum hydrocarbons

TRPH = total recoverable petroleum hydrocarbons

ug/L = micrograms per liter

"<" = not detected at or above laboratory reporting limit

--- = not analyzed

B = compound was found in the blank and sample.

H = sample was prepped or analyzed beyond the specified holding time.

UN = compound was found in the blank and sample and result should be viewed as tentative non detection (i.e. suspect)

J = Result is less than the reporting limit (RL) but greater than or equal to the method detection limit (MDL) and the concentration is an approximate value

1.0 INTRODUCTION

This Appendix to the Remedial Action Plan (RAP) describes the screening-level human health risk assessment (SLHHRA) conducted to support the proposed remedial/mitigation measures and risk management decisions as outlined in the RAP for the former Santa Rosa Manufactured Gas Plant (MGP) site (“the Site”), located at 111 Santa Rosa Avenue in Santa Rosa, California. The Site location is shown in Figure 1. The primary purpose of the SLHHRA is to determine whether levels of chemicals detected in soil at the Site could pose a risk to human health based on current and potential future property uses. The results of the SLHHRA may then be used to identify areas of the Site where remedial/mitigation measures and/or risk management may be appropriate, with the overall goal of long-term protection of human health.

The methodology used in this SLHHRA is consistent with risk assessment guidelines provided by the U.S. Environmental Protection Agency’s (USEPA) *“Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual (Part A), Interim Final”* (USEPA, 1989a), and the California Environmental Protection Agency (Cal/EPA), Department of Toxic Substances Control’s (DTSC) *“Preliminary Endangerment Assessment Guidance Manual”* (Cal/EPA, 2013). The approach used in this SLHHRA, in general, follows the traditional steps in the risk assessment process, employing the use of risk-based screening concentrations (RBSCs) and ambient-based screening concentrations (ABSCs) to evaluate potential human health risks.

The remaining sections of this report are as follows:

- Section 2.0 – Data Evaluation and Selection of Chemicals of Potential Concern. Presents an evaluation of the data used in the SLHHRA and identifies the chemicals of potential concern (COPCs).
- Section 3.0 – Exposure Assessment. Presents an analysis of the mechanisms by which human receptors may be exposed to COPCs and discusses the representative exposure point concentrations (EPCs) used in this SLHHRA to evaluate potential health risks.
- Section 4.0 – Selection of Risk-Based Screening Concentrations. Presents the quantitative RBSCs developed by USEPA and Cal/EPA considered protective of the potentially complete exposure pathways and receptors identified in Section 3.0. For select COPCs such as CPAHs and arsenic, where RBSCs are lower than ambient levels, ABSCs are presented.
- Section 5.0 – Comparison of Soil RBSCs and ABSCs to Soil EPCs. Presents a comparison of EPCs for COPCs in soil to RBSCs and ABSCs to evaluate the potential for cancer or other adverse health effects as a result of potential exposures.
- Section 6.0 – Conclusions and Recommendations. Summarizes the results of the HHRA and provides context for risk management and consideration of potential mitigation options.
- Section 7.0 – References. Presents the sources of information cited in the text.

There is one attachment that accompanies the SLHHRA; Attachment A presents output from USEPA's ProUCL 5.0.00 (USEPA, 2013a), used to determine upper confidence limit (UCL) concentrations from the on-Site and off-Site soil data.

2.0 DATA EVALUATION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN

Data evaluation is the process of analyzing site characteristics and analytical data to identify constituents that are potentially related to the Site and for which there are data of sufficient quality to be used in a quantitative risk assessment. This section summarizes: (1) the chemical characterization of soil (i.e., the relevant environmental medium for this SLHHRA); and (2) the COPCs identified for inclusion in the SLHHRA.

2.1 Development of SLHHRA Datasets

Site investigations began in July 1986 and remedial actions were initiated at the Site as early as 1987. Investigation and remedial actions have been conducted at the Site through June 2013. A detailed summary of previous investigations and remedial measures conducted at the Site is provided in Sections 1.4 and 1.5, respectively, of the RAP. As described in Section 1.1 of the RAP, the Site currently consists of the parking lot, a commercial office building located at 111 Santa Rosa Avenue, and a portion of the Prince Memorial Greenway (PMG) (Figures 2 and 3). Previous Site investigations and/or remedial actions have been conducted beyond the property boundaries of the Site in the adjacent commercial property to the west of the Site and in the adjacent public rights-of-way (ROW) to the north, east, and south. Analytical data included in the SLHHRA consist of representative soil data (i.e., from samples from locations and/or depths that have not been remediated) collected during previous Site investigations and/or remedial actions conducted at the Site and off-Site areas. The locations of the in-place soil samples representative of current on-Site and off-Site conditions are presented on Figure 3. Analytical results for volatile organic compounds (VOCs), total petroleum hydrocarbons (TPH), total polychlorinated biphenyls (PCBs), metals, cyanide, and semi-volatile (SVOCs) including polycyclic aromatic hydrocarbons (PAHs), representative of in-place soil, are presented in Tables 1 through 4 of the RAP.

Soil data considered relevant for a SLHHRA that includes future land use scenarios typically include all available data for soil samples from depths up to and including 10 feet below ground surface (bgs) or first encountered groundwater, whichever is shallower, because: (1) 10 feet is considered a typical maximum depth for excavation activities associated with subsurface maintenance/landscaping work or site redevelopment, and (2) the models and assumptions used to evaluate potential exposures are not directly applicable for saturated soils. Groundwater at the Site has been reported to occur at approximately 20 feet bgs, and groundwater levels are generally responsive to seasonal variations in precipitation and vary as much as a few feet seasonally (TPG, 2013). Given the depth of groundwater, the analytical results for all constituents detected in soil samples from the soil surface (0 feet bgs) to 10 feet bgs are considered relevant for the SLHHRA.¹

¹ Site soil analytical data were provided to Iris Environmental in a database format by Terra Pacific Group. Soil samples where the location coordinates were unknown are excluded from the dataset used in the SLHHRA (i.e., 450 out of 10,704 data records [or 4.2 percent] for in-place soil from 0-10 feet bgs). Also,

For the purposes of supporting risk management decisions, separate data subsets were prepared and evaluated in the SLHHRA for: 1) the on-Site Property (i.e., the 111 Santa Rosa Avenue Property); 2) the off-Site 438 First Street Property; and 3) the off-Site public ROW (inclusive of the PMG).

2.2 Selection of Chemicals of Potential Concern

COPCs included in the SLHHRA are those constituents detected above laboratory reporting limits in at least one soil sample. Although Cal/EPA and USEPA guidance allow for the elimination of inorganic constituents (i.e., metals) from the quantitative risk assessment if they are detected at levels within local background/ambient concentrations (Cal/EPA, 1997; USEPA, 2002a), all chemicals detected in on-Site and off-Site soil samples have been conservatively included in the quantitative SLHHRA to streamline the evaluation. The COPCs detected in on-Site and off-Site soil that are included in the quantitative SLHHRA include 13 VOCs, 6 TPH, total PCBs, 17 PAHs, and 19 inorganics. The specific COPCs detected in soil are as follows:

- **VOCs:** 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, 2-butanone (MEK), 4-isopropyltoluene, acetone, benzene, butylbenzene, ethylbenzene, methyl-t-butyl ether (MTBE), naphthalene, propylbenzene, toluene and xylenes;
- **TPH:** oil and grease, TPH as extractable (TPH-extractable), total recoverable petroleum hydrocarbons, TPH as gasoline (TPH-gasoline) TPH as diesel (TPH-diesel), and TPH-motor oil;
- **PCBs:** total PCBs;
- **PAHs:** 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene [B(a)P], benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-c,d)pyrene, naphthalene, phenanthrene, and pyrene; and
- **Inorganics:** ammonia, antimony, arsenic, barium, beryllium, cadmium, chromium, copper, cyanide, lead, mercury, molybdenum, nickel, selenium, silver, vanadium, thallium, titanium, and zinc.

Data summaries for the COPCs in on-Site Property soil (0-10 feet bgs), off-Site 438 First Street Property soil (0-10 feet bgs), and off-Site public ROW soil (0-10 feet bgs) are presented in Tables 1a through 1c, respectively.

soil analytical data reported as non-detect (ND) without a laboratory reporting limit in previous investigation reports are excluded from the dataset used in the SLHHRA (i.e., 14 out of 10,704 data records [or 0.13 percent] for in-place soil from 0-10 feet bgs).

3.0 EXPOSURE ASSESSMENT

Exposure assessment is the process of describing, measuring, or estimating the intensity, frequency, and duration of potential human exposure to COPCs in environmental media. This section discusses the mechanisms by which people (receptors) might come in contact with the COPCs present in soil at the Site. It includes the characterization of the exposure setting (physical environment and potential receptors), identification of exposure pathways (potential sources, points of release, and exposure routes), and quantification of representative EPCs based on current and potential future land uses.

An exposure assessment is best conducted within the context of a risk-based conceptual site model (CSM) (Figure 4). The CSM is used to show the relationships between a chemical source, exposure pathway, and the potential receptor. The CSM identifies chemical sources, potentially impacted media, migration pathways, exposure routes, and possible exposure scenarios (USEPA, 1989a). These source-pathway-receptor relationships provide the basis for the quantitative exposure assessment. Only complete source-pathway-receptor relationships are included in the SLHHRA.

3.1 Characterization of Exposure Setting

Potential exposure to COPCs at a site depends on a number of factors related to the physical characteristics of a site and its surroundings. These factors include location, surrounding land use, surface topography, hydrogeology, meteorology, and vegetation. They also include factors related to the current and possible future uses of a site, which determine the types of activities that might occur at a site, the degree to which a site is accessible to the general public, and the mechanisms that might result in migration of COPCs to on- and off-Site populations.

3.1.1 Physical Setting

As summarized in Section 1.1 of the RAP, the Site occupies approximately 1.5 acres and is located in Santa Rosa, California, between First Street and Santa Rosa Creek, and B Street and Santa Rosa Avenue (Figure 2). The Site currently consists of a parking lot, a commercial office building located at 111 Santa Rosa Avenue, and a portion of the PMG (Figure 3). Commercial office buildings are present to the east, west, and north (across 1st Street) of the Site. The PMG is to the south of the Site. The Site surface is covered with asphalt pavement in the parking lot, small landscaped planters, a portion of the commercial office building, and the concrete walkway of the PMG. The off-Site 438 First Street Property surface is covered with asphalt pavement in the parking lot with small landscaped planters and a commercial building. The off-Site public ROW surface is covered with concrete sidewalks, asphalt pavement in the streets, and concrete walkway and adjacent planters of the PMG. The small on-Site landscaped planters and the shared landscaped planters on the western and southern boundaries of the Site that extend onto the off-Site 438 First Street Property and the PMG were remediated in May and June 2013, down to approximately 2 feet bgs and a geotextile marker was placed at

the bottom of the excavation to prevent direct exposure to subsurface impacted soil. The commercial office building located on a portion of the Site has an underground parking garage with an automated rollup door entry; exhaust fumes are ventilated with fans inside the garage.

3.1.2 *Potential Receptors*

Populations identified in this SLHHRA include those who could potentially receive the most exposure to Site-related chemicals under current or foreseeable future land use scenarios (USEPA, 1989a). Under current Site use, potentially exposed receptors include on-Site commercial workers and infrequent visitors. However, given that the overall exposure that an infrequent visitor could potentially have to COPCs in soil at the Site would be considerably less than that for a commercial worker who completes standard 8-hour day shifts 5 days per week, potential human health risks to infrequent visitors are not separately evaluated. The current on-Site commercial worker is evaluated as protective of both receptors.

Although the on-Site Property will likely remain in its current commercial configuration in the future, this SLHHRA also assumes that the Site could alternatively be redeveloped for other commercial uses. Potentially exposed receptors identified for the SLHHRA, therefore, include hypothetical future on-Site commercial workers². The future on-Site commercial worker is evaluated to provide support for the remedial/mitigation measures described in the RAP. In addition, while future residential land use of the Site is not anticipated given the current and surrounding commercial property uses, hypothetical future on-Site residents are also evaluated, primarily for informational purposes and to provide the basis for a deed restriction on the Site, if warranted.

In sum, based on the current and assumed hypothetical future uses of the on-Site Property, the populations included in the SLHHRA consist of the following:

- Current on-Site worker (also evaluated as protective of infrequent visitors);
- Hypothetical future on-Site commercial worker; and
- Hypothetical future on-Site resident.

Similar to the on-Site Property, the off-Site 438 First Street Property and off-Site public ROW areas are evaluated under hypothetical future commercial worker and residential scenarios, to provide the basis for any remedial/mitigation measures and/or deed restrictions, if warranted, for these areas.

² The future on-Site commercial scenario evaluated in the SLHHRA is protective of a construction/intrusive worker scenario. Given that the overall exposure that a short-term construction/intrusive worker could potentially have to COPCs in soil at the Site would be less than that for a commercial worker who completes standard 8 hour day shifts 5 days per week for 25 years, potential human health risks to a construction/intrusive worker are not separately evaluated. The future on-Site commercial worker is evaluated as protective of both receptors.

3.2 Identification of Exposure Pathways

This section describes the potential pathways by which the receptors described above could be exposed to the COPCs in soil at the Site. An exposure pathway is a description of the mechanism by which an individual may come into contact with a COPC in the environment. An exposure pathway is defined by the following four elements (USEPA, 1989a):

1. Source and mechanism of COPC release to the environment;
2. Environmental receiving or transport medium (e.g., soil) for the released COPC;
3. Point of potential contact with the medium of concern; and
4. Potential exposure route (e.g., ingestion) at the contact point.

An exposure pathway is considered “complete” if all of the foregoing elements are present.

The characterization of the potential exposure pathways based on existing information is presented in the CSM (Figure 4). Further discussion of potential exposure pathways is presented in the following subsections.

3.2.1 Chemical Sources and Potential Transport Mechanisms

For the purposes of this SLHHRA, former MGP facility operations were considered the primary source of COPCs in soil. Chemicals released into the surface and subsurface soils have the potential to migrate to other areas or to other media by potential secondary release mechanisms based on their inherent physical nature, including volatilization into air, wind erosion and atmospheric dispersion of nonvolatile, particulate-bound constituents, and subsurface migration of constituents into groundwater.

3.2.2 Complete Exposure Pathways

Complete exposure pathways for the identified receptors require an exposure point for contact with the COPCs and human exposure routes. As mentioned previously in Section 3.1.1, the majority of the Site surface is currently covered with asphalt pavement in the parking lot, a portion of the commercial office building with an underground parking garage, and the concrete walkway of the PMG; all of these physical features prevent direct exposure to subsurface impacted soil. Furthermore, the small landscaped planters in the on-Site and off-Site 438 First Street Property parking lots were remediated down to 2 feet bgs and a geotextile marker was placed at the bottom of the excavation to prevent direct exposure to subsurface impacted soil. Under current Site conditions, on-Site commercial workers could potentially be exposed via inhalation to volatile constituents that have migrated through the soil column into the outdoor air. Although this is theoretically a complete exposure pathway for current on-Site commercial workers, this pathway is considered an insignificant exposure pathway, as discussed in the section below.

For the purposes of supporting risk management decisions, this SLHHRA assumes that hypothetical future receptors (on-Site commercial workers and residents) could be exposed to COPCs in soil via incidental ingestion, dermal contact, and inhalation of COPCs volatilized or re-suspended as respirable particulates in outdoor air.

3.2.3 *Insignificant/Incomplete Exposure Pathways*

Exposure pathways considered insignificant or incomplete for current on-Site populations were not included in the risk evaluation and are discussed below:

- Exposures related to direct contact with subsurface impacted soil: As discussed above, the current Site current cover prevents direct exposure to subsurface impacted soil. Therefore, exposure to COPCs in soil via the ingestion and dermal contact pathways as well as inhalation of particulates in outdoor air pathway are considered incomplete for the current on-Site commercial worker and not included in this SLHHRA.
- Exposures related to volatilization and migration to indoor air (vapor intrusion): Vapor intrusion, the process whereby volatile compounds in subsurface media volatilize and migrate up through the soil column into the indoor air space of an overlying building, is considered an insignificant transport/exposure pathway under current land use conditions at the Site. As shown on Figure 2, less than one tenth of the commercial building is within the footprint of the former MGP, and there are no other structures on-Site. As mentioned previously, the commercial building has a single story underground parking. Thus, soil impacts within the footprint of the commercial building, if they existed, would have been excavated and removed when the underground parking garage was constructed. The underground parking garage has an automated rollup door entry and exhaust fumes are ventilated with fans inside the garage. The underground garage is a physical feature that would minimize the potential for vapor intrusion, even in the unlikely event that there were a source of VOCs that remained beneath the underground garage. Based on the extremely limited potential for there to be any Site-related source of VOCs beneath the building, combined with the presence of the subsurface garage, the vapor intrusion pathway is considered insignificant for the commercial occupants of the current building and not included in this SLHHRA.
- Exposures related to volatilization and migration of volatiles to outdoor air: Volatile compounds in subsurface media could volatilize and migrate up through the soil column into the outdoor ambient air, and then current on-Site commercial workers (and visitors) could be exposed via the inhalation pathway. Perimeter air monitoring for volatile compounds has been conducted throughout the period of Site remediation in the area of the former redwood gas holder where elevated VOCs were detected in soil. The monitoring data, collected daily over a 2-year period, support that even during this remediation phase, the levels of volatile compounds in ambient air were below levels of concern with respect to the health of on-Site and nearby off-site populations (TPG, 2014). The air monitoring data support that the levels of volatile compounds in ambient air are fully protective of

the health of off-Site as well as on-Site populations. Therefore, the inhalation of vapors in outdoor air pathway is considered insignificant for the current on-Site commercial workers (and visitors) and not included in this SLHHRA.

- Exposures related to groundwater: Groundwater is approximately 20 feet bgs, and currently not used as a drinking water source on-Site. As noted in the Groundwater Feasibility Study (TPG 2015), the remedy for the Site includes long-term groundwater monitoring and deed restrictions that will prevent the use of groundwater in the future. Accordingly, direct contact exposure pathways related to Site groundwater are considered incomplete and not included in this SLHHRA.
- Exposures related to migration of groundwater to the surface water in Santa Rosa Creek: As discussed in the Groundwater Feasibility Study for the Site (TPG, 2015), during the removal activities of impacted soil in the bank and bed of Santa Rosa Creek in 2004, sheet pile and slurry curtains were installed at various locations along the bank of the creek. These barriers, in conjunction with the creek bed lining, restrict groundwater flow within the shallow soil adjacent to the creek, reducing the potential for residual contaminants present at the Site to migrate towards the creek. Further, historic and recent groundwater data collected from the Site indicate that current groundwater impacts are limited to areas where residual MGP impacts are known to be present and there is no indication that Site contaminants are migrating to the creek. The North Coast Regional Water Quality Control Board (NCRWQCB, 2015) has concurred that remaining contamination near the creek does not present a significant threat to the creek and the selected groundwater remedy of long-term groundwater monitoring is an appropriate technology that will achieve the project's remedial action goals. Therefore, potential exposures associated with migration of groundwater to the surface water in the adjacent Santa Rosa Creek are considered incomplete and not included in this SLHHRA.

3.3 Estimation of Representative Exposure Point Concentrations

The USEPA defines EPCs as the representative chemical concentrations that a receptor may contact at an exposure area over the exposure period (USEPA, 1989a). The EPC approach is based on the concept that individuals contact the impacted medium on a periodic and random basis. Because of the repeated and random nature of such contact, human exposure does not occur at a fixed point, but rather at a variety of points with equal likelihood that any given point within the exposure area will be the contact location on any given day. Thus, the EPC is based on an average chemical concentration within the exposure area. To account for the uncertainty in estimating the average concentration, USEPA recommends that a UCL be used to represent the EPCs (USEPA, 2002b).

The calculation of EPCs for each COPC dataset includes an initial evaluation of the distribution of the data as a predecessor step to employing the best statistical methodology for determining a concentration that estimates the mean of the dataset with a prescribed level of confidence. This means that the average has been bounded by a

statistically determined concentration to afford a percent level of confidence in the “true” mean of the dataset. USEPA’s ProUCL 5.0.00 (USEPA, 2013a) is used to determine UCL concentrations of the COPCs in soil (0-10 feet bgs). The 95% UCL of the mean, for example, is considered a reasonable maximum exposure level (USEPA, 1989a) so that there is confidence that the mean concentration of each COPC has been bounded at least 95 percent of the time. In accordance with USEPA guidance (USEPA, 2013b), UCLs are not calculated for datasets with less than four detections. Although USEPA guidance (USEPA, 2013b) recommends the use of the mean or median when there are insufficient detections in the dataset, the maximum detected concentration is conservatively used as the representative EPC in these cases in this SLHHRA.

Data summaries for the COPCs in on-Site Property soil (0-10 feet bgs), off-Site 438 First Street Property soil (0-10 feet bgs), and off-Site public ROW soil (0-10 feet bgs) are presented in Tables 1a through 1c, respectively, with the ProUCL output files presented in Attachment A.

4.0 SELECTION OF RISK-BASED AND AMBIENT-BASED SCREENING CONCENTRATIONS

4.1 Risk-Based Screening Concentrations

As discussed previously in Section 3.2.3, the potential pathways through which current on-Site commercial workers could be exposed to COPCs at the Site are considered either incomplete or insignificant. Therefore, the current Site conditions are fully protective of the current on-Site commercial populations.

For the purposes of supporting risk management decisions, hypothetical future receptors (on-Site commercial workers and residents) are assumed to be exposed to COPCs in soil via incidental ingestion, dermal contact, and via inhalation of COPCs volatilized or re-suspended as respirable particulates in outdoor air. Potential human health risks for the future hypothetical receptors identified above are evaluated using RBSCs protective of the exposure pathways identified as potentially complete for these receptors. Specifically, Regional Screening Levels (RSLs) developed by the USEPA (2014) for industrial soil are considered to be applicable cancer-based and noncancer-based criteria for hypothetical future commercial workers, and RSLs for residential soil are considered applicable cancer-based and noncancer-based criteria for hypothetical future residents. These screening benchmarks are based on reasonable maximum exposure assumptions for industrial or residential land use – specifically, exposure to COPCs in soil via incidental soil ingestion, dermal contact with soil, and inhalation of volatiles or particulates in outdoor air, for 250 days per year for 25 years for industrial workers, or 350 days per year for 26 years for residents – corresponding to a target incremental lifetime excess cancer risk (ILECR) of one in one million (1×10^{-6}) (i.e., Cal/EPA’s point of departure for ILECR for all receptor groups)³ or a target noncancer hazard quotient (HQ) of 1.⁴ Cal/EPA’s HHRA Note Number 3 (Cal/EPA, 2014) was also consulted for recommended alternatives to RSLs to ensure the SLHHRA conforms to Cal/EPA risk assessment guidance (Cal/EPA, 2013). The RSLs and Cal/EPA’s HHRA Note Number 3 alternative screening values are by design protective of potential on-Site industrial or residential soil exposure via incidental ingestion, dermal contact, and outdoor air inhalation. RSLs and Cal/EPA’s HHRA Note Number 3 alternative screening values were selected for use in the SLHHRA over California Regional Water Quality Control Board, San Francisco Bay Region (SFRWQCB) Environmental Screening Levels (ESLs) for direct contact exposure pathways for industrial and residential populations because

³ The National Contingency Plan (NCP) (40 Code of Federal Regulations [CFR] 300) indicates that ILECRs posed by a site should not exceed a range of 1×10^{-6} to one hundred in a million (1×10^{-4}). While Cal/EPA’s point of departure for ILECR for all receptor groups (i.e., commercial/industrial worker and residential populations) is 1×10^{-6} , risk management decisions may raise this criterion depending on site-specific conditions. For instance, the “target” cancer risk typically used by Cal/EPA and USEPA in determining the need for mitigation is 1×10^{-5} for worker populations on commercial/industrial sites.

⁴ Chemical exposures that yield hazard indices (HIs) of less than 1 are not expected to result in adverse noncancer health effects (USEPA, 1989a).

the current RSLs incorporate the latest USEPA exposure assumption recommendations, whereas the ESLs do not.

In the absence of RSLs for TPH mixtures, direct exposure ESLs developed by the SFRWQCB for TPH as gasoline, diesel and motor oil (SFRWQCB, 2013) were selected to evaluate potential exposures to these mixtures in soil.

Note that the Cal/EPA-recommended screening levels for lead are unique from the cancer-based and noncancer-based RBSCs selected for the other COPCs and are based on blood lead concentrations rather than external dose (Cal/EPA, 2014).

The commercial land use RBSCs selected for the hypothetical future commercial worker, and the residential land use RBSCs selected for the hypothetical future resident for the COPCs in on-Site Property soil (0-10 feet bgs), off-Site 438 First Street Property soil (0-10 feet bgs), and off-Site public ROW soil (0-10 feet bgs), using the hierarchy presented above, are presented in Tables 2a through 2c, respectively.

4.2 Ambient-Based Screening Concentrations

Given that risk-based residential cleanup goals for carcinogenic PAHs (CPAHs⁵) and arsenic in soil are below ambient concentrations, the numerical remedial goal for these compounds would not be risk-based, but rather would be based on the ambient concentrations of CPAHs and arsenic.

In order to facilitate the development of an ambient background data set for CPAHs in northern California, a dataset was compiled from previous site investigations in northern California conducted under the oversight of DTSC by PG&E and the United States Navy. The dataset was developed in cooperation and collaboration with a task group of representatives from the HERD and Site Mitigation branches of DTSC, Cal/EPA. The team of consulting firms involved in the development of the database were ENVIRON, Entrix, Iris Environmental, and ENV America. The final dataset consists of eighty-six data points from twenty-one different sites. The details of this study are presented in a report that was submitted to HERD June 7, 2002 (ENVIRON et al., 2002). Multiple analyses conducted in the study demonstrate that the final dataset is consistent with a lognormal distribution and support the hypothesis that the final dataset represents a single background population. The arithmetic mean and the 95% UCL of the mean of the background CPAH dataset, in B(a)P equivalents, are 0.21 mg/kg and 0.40 mg/kg, respectively.

DTSC has issued an Advisory (Cal/EPA, 2009) that supports the use of the PAH background dataset as a tool for assessing PAH impacts and making remediation

⁵ Benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-c,d)pyrene are collectively referred to as CPAHs. The concentrations of these CPAHs were converted into B(a)P equivalent concentrations for purposes of assessing potential health risks associated with CPAHs in soils. Although naphthalene is also carcinogenic, it is a volatile PAH and thus, is evaluated separately in this SLHRA.

decisions for PAHs at sites. Consistent with the approaches used at other sites, and with the approach often used for determining ambient-based remediation targets for inorganics, an upper tolerance limit (UTL) of the ambient distribution is often proposed as the initial remediation target for the Site. The USEPA has described the calculation of the UTL, and has suggested its use for groundwater monitoring activities (USEPA, 1989b), although it is applicable to performing background comparisons for soil samples as well. The approach used in calculating the UTL is consistent with the approach recommended by the USEPA (1989b).

The 95% UTL (95% coverage and 95% confidence) of the 86 background sample dataset is 1.5 mg/kg (in B(a)P equivalents). Because the coverage of the UTL is set at 95%, approximately 5% of samples that are actually representative of ambient concentrations will be greater than the UTL of 1.5 mg/kg.

Another parameter that is commonly used in establishing ambient-based remediation targets is the 95th percentile of the distribution. Measured concentrations that are below the 95th percentile are considered to be ambient. The DTSC has recommended the use of the 95th percentile for determining ambient levels of metals at former military bases. The 95th percentile of the northern California background dataset is 0.92 mg/kg (in B(a)P equivalents). Because the 95th percentile is lower than the UTL of the data, we propose to use 0.92 mg/kg as the initial ABSC B(a)P equivalents to identify areas of the Site for either remediation or other forms of risk management. Concentrations below the initial background-based screening concentration ABSC of 0.9 mg/kg will be considered representative of ambient concentrations, and will not initially be targeted for remediation or other forms of risk management.

An evaluation of Site arsenic data and a determination of an ambient arsenic level were previously conducted for the planter area remediation, per Cal/EPA guidance (2009b). The evaluation is presented in Appendix B of the Planter Area Soil Excavation Workplan for the Site (TPG, 2012). The ABSC for arsenic at the Site was determined to be 14 mg/kg.

ABSCs for CPAHs and arsenic in on-Site Property soil (0-10 feet bgs), off-Site 438 First Street Property soil (0-10 feet bgs), and off-Site public ROW soil (0-10 feet bgs) are presented in Tables 2a through 2c, respectively.

5.0 COMPARISON OF SOIL RBSCS AND ABSCS TO SOIL EPCS

As previously mentioned, the Site conditions are fully protective of the health of current on-Site populations. For the purposes of supporting risk management decisions, potential human health risks for the future hypothetical receptors (on-Site commercial and residential populations) have been evaluated using RBSCs and ABSCs protective of the exposure pathways identified as potentially complete for these receptors. A comparison of RBSCs and ABSCs to EPCs for COPCs in soil has been used to determine whether levels of chemicals detected in soil at the on-Site Property, off-Site 438 First Street Property, and off-Site public ROW could pose a risk to human health above acceptable risk and hazard levels based on potential future property uses. The results of the comparison may be used to support the remedial/mitigation measures and deed restrictions proposed in the RAP. The results of the comparison of soil RBSCs and ABSCs to soil EPCs are discussed below.

5.1 On-Site Property

As indicated on Table 2a, the EPCs for benzene, naphthalene, TPH-diesel, and lead in on-Site Property soil (0-10 feet bgs) exceed the lower of either the cancer or noncancer commercial soil RBSCs by a factor ranging from 1.5 (TPH-diesel; noncancer RBSC) up to 41 (naphthalene, cancer RBSC). Individual detections of COPCs that exceed commercial soil RBSCs, as summarized in Table 3a, are scattered across the parking lot area of the on-Site Property.

The EPCs for benzene, ethylbenzene, naphthalene, TPH-diesel, total PCBs and lead in on-Site Property soil (0-10 feet bgs) exceed the lower of either the cancer or noncancer residential soil RBSCs by a factor ranging from 2.2 (ethylbenzene; cancer RBSC) up to 183 (naphthalene; cancer RBSC). Individual detections of COPCs that exceed residential soil RBSCs, as summarized in Table 3a, are scattered across the parking lot area of the on-Site Property.

The EPCs for CPAHs (expressed as B(a)P equivalents) and arsenic in on-Site Property soil (0-10 feet bgs) exceed their respective ABSCs by a factor of 39 and 1.5, respectively. Individual detections of COPCs that exceed ABSCs, as summarized in Table 3a, are scattered across the parking lot area of the on-Site Property.

5.2 Off-Site 438 First Street Property

As indicated on Table 2b, the EPC for lead in off-Site 438 First Street Property soil (0-10 feet bgs) exceeds its noncancer commercial soil RBSC by a factor of 1.5. As summarized in Table 3b, there is only one detection of lead in the shared planter area on the eastern boundary of the off-Site 438 First Street Property that exceeds its commercial soil RBSC. The sample is at depth (2 feet bgs), below the geotextile barrier put in place following the remediation of the planter areas.

The EPC for lead in off-Site 438 First Street Property soil (0-10 feet bgs) exceeds its noncancer residential soil RBSC by a factor of 6.0. As summarized in Table 3b, there are four detections of lead in the shared planter area, on the eastern boundary of the off-Site 438 First Street Property, that exceed the residential soil RBSC. The samples are at depth (all at 2 feet bgs), below the geotextile barrier put in place following the remediation of the planter areas.

The EPC for arsenic in off-Site 438 First Street Property soil (0-10 feet bgs) exceeds its ABSC by a factor of 2.6. As summarized in Table 3b, there is only one detection of arsenic in the shared planter area on the eastern boundary of the off-Site 438 First Street Property that exceeds its ABSC. The sample is at depth (2 feet bgs), below the geotextile barrier put in place following the remediation of all planters.

5.3 Off-Site Public ROW

As indicated on Table 2c, the EPC for naphthalene in off-Site public ROW soil (0-10 feet bgs) exceeds the lower of either its cancer or noncancer commercial soil RBSCs by a factor of 2.8. Individual detections of naphthalene that exceed its commercial soil RBSC, as summarized in Table 3c, are along the PMG. There are no exceedances in the sidewalks or streets to the north or east of the Site.

The EPCs for naphthalene and lead in off-Site public ROW soil (0-10 feet bgs) exceed the lower of either the cancer or noncancer residential soil RBSCs by a factor of 12 and 1.7, respectively. Individual detections of naphthalene and lead that exceed residential soil RBSCs, as summarized in Table 3c, are along the PMG. There are no exceedances in the sidewalks or streets to the north or east of the Site.

The EPC for CPAHs (expressed as B(a)P equivalents) in off-Site public ROW soil (0-10 feet bgs) exceeds its ABSC by a factor of 283. Individual detections of CPAHs exceed its ABSC, as summarized in Table 3c, are along the PMG. There are no exceedances in the sidewalks or streets to the north or east of the Site.

6.0 CONCLUSIONS AND RECOMMENDATIONS

The primary purpose of the SLHHRA is to determine whether levels of chemicals detected in soil at the Site could pose a risk to human health based on current and potential future property uses. The results of the SLHHRA may then be used to identify areas of the Site where remedial/mitigation measures and/or risk management may be appropriate, with the overall goal of long-term protection of human health. The conclusions and recommendations of the SLHHRA, based on the current and potential future property uses, are summarized below.

6.1 Current Land Use

Under current Site conditions, the potential pathways through which on-Site commercial workers could be exposed to COPCs in soil are considered incomplete or insignificant. Therefore, the current Site conditions are fully protective of the health of current on-Site commercial populations and no further remedial or mitigation measures are warranted. Risk management measures, such as a cap maintenance/soil management plan and deed restrictions, are warranted to ensure that the Site continues to remain protective of human health.

6.2 Potential Future Land Uses

For the purposes of supporting risk management decisions, a comparison of RBSCs and ABSCs to EPCs for COPCs in soil was used to evaluate potential human health risks under potential future land use scenarios. The following are the conclusions and recommendations for the on-Site Property, off-Site 438 First Street Property, and off-Site public ROW under hypothetical future commercial and residential land use scenarios.

6.2.1 On-Site Property

The results of the comparison of EPCs for COPCs in on-Site Property soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicate that levels of arsenic, benzene, CPAHs, naphthalene, TPH-diesel, and lead are above levels suitable for future commercial land use if the Site were to be redeveloped for other commercial uses (e.g., if the existing cover were to be removed, and/or if a building were to be constructed elsewhere on-Site). Accordingly, risk management measures, such as a cap maintenance/soil management plan and a deed restriction, are warranted for the protection of future commercial populations at the on-Site Property.

The results of the comparison of EPCs for COPCs in on-Site Property soil (0-10 feet bgs) to residential soil RBSCs and ABSCs indicate that levels of arsenic, benzene, CPAHs, ethylbenzene, naphthalene, TPH-diesel, total PCBs, and lead are above acceptable levels suitable for future residential land use if the Site were to be redeveloped for residential use. Accordingly, risk management measures that restrict the future residential use of the property are warranted for the on-Site Property.

6.2.2 *Off-Site 438 First Street Property*

The results of the comparison of EPCs for COPCs in off-Site 438 First Street Property soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicate that levels of arsenic and lead at depths greater than 2 feet bgs in the small landscaped planter areas along the eastern boundaries of the property are above levels suitable for future commercial land use if this property were to be redeveloped for other commercial use. Accordingly, risk management measures such as a cap maintenance/soil management plan for soil below 2 feet bgs in the planter areas are warranted for the protection of future commercial populations at the off-Site 438 First Street Property.

The results of the comparison of EPCs for COPCs in off-Site 438 First Street Property soil (0-10 feet bgs) to residential soil RBSCs and ABSCs indicate that levels of arsenic and lead at depths greater than 2 feet bgs in the small landscaped planter areas along the eastern boundaries of the property are above levels suitable for future residential land use if the Site were to be redeveloped for residential use. Accordingly, risk management measures that restrict the future residential use of the property are warranted for the off-Site 438 First Street Property.

6.2.2 *Off-Site Public ROW*

The results of the comparison of EPCs for COPCs in off-Site public ROW soil (0-10 feet bgs) to commercial soil RBSCs and ABSCs indicate that levels of CPAHs and naphthalene are above levels suitable for future commercial land use (e.g., if the existing cover in the off-Site public ROW, specifically along the PMG, were to be removed). Accordingly, risk management measures are warranted to ensure that impacts that remain in the PMG are properly managed.

The results of the comparison of EPCs for COPCs in off-Site public ROW soil (0-10 feet bgs) to residential soil RBSCs and ABSCs indicate that levels of CPAHs, naphthalene, and lead along the PMG are above levels suitable for future residential land use. Accordingly, risk management measures are warranted to ensure that impacts that remain in the PMG are properly managed.

Selenium	1 / 68	0.71	1.0	NC	0.71
Silver	6 / 73	0.60 - 1.2	0.33	0.31	0.31
Thallium	5 / 68	0.56 - 0.79	0.62	0.54	0.54
Titanium	5 / 5	5.0 - 6.0	5.4	NC	6.0
Vanadium	68 / 68	25 - 110	53	56	56
Zinc	77 / 77	37 - 995	167	247	247

Notes:

a = Upper confidence limits (UCLs) on the arithmetic mean derived using ProUCL 5.0 (U.S. Environmental Protection Agency [USEPA], 2013a); ProUCL output is presented in Attachment A.

b = Where calculated, estimated UCLs on the arithmetic mean were selected as representative exposure point concentrations (EPCs) for the human health risk assessment (HHRA), consistent with USEPA guidance (2002). Maximum detected concentrations (**BOLDED**) are alternatively conservatively used as representative EPCs.

mg/kg = milligrams per kilogram

NC = Not calculated. In order for ProUCL 5.0 to reliably evaluate a specific data population (e.g., dataset of concentrations of a particular chemical measured at the site), the population must include at least ten results including at least four detections (USEPA, 2013b).

ND = Not detected.

Notes:

ABSC = Ambient-Based Screening Concentration.

RBSC = Risk-Based Screening Concentration.

na = Carcinogenic PAHs (CPAHs) evaluated using benzo(a)pyrene equivalency method.

-- = Not applicable.

a = Surrogate value - assumes RBSC for acenaphthene.

b = Surrogate value - assumes RBSC for pyrene.

c = Surrogate value - assumes RBSC for anthracene.

d = Ratio of exposure point concentration (EPC) Over RBSC or ABSC is **BOLDED**.

Notes:

ABSC = Ambient-Based Screening Concentration.

RBSC = Risk-Based Screening Concentration.

na = Carcinogenic PAHs (CPAHs) evaluated using benzo(a)pyrene equivalency method.

-- = Not applicable.

a = Surrogate value - assumes RBSC for acenaphthene.

b = Surrogate value - assumes RBSC for pyrene.

c = Surrogate value - assumes RBSC for anthracene.

d = Ratio of exposure point concentration (EPC) Over RBSC or ABSC is **BOLDED**.

95% Gamma Approximate KM-UCL (use when n>=50)	6.611	95% Gamma Adjusted KM-UCL (use when n<50)	6.73

Gamma (KM) may not be used when k hat (KM) is < 0.1

Gamma ROS Statistics using Imputed Non-Detects

ATTACHMENT A
ESTIMATION OF REPRESENTATIVE EXPOSURE POINT CONCENTRATIONS FOR CHEMICALS OF
POTENTIAL CONCERN IN ON-SITE PROPERTY SOIL (0-10 FEET BGS) - PROUCL OUTPUT
Former Santa Rosa MGP Site
Santa Rosa, California

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	5.0000E-4	Mean	1.075
Maximum	120	Median	0.01
SD	9.927	CV	9.235

Lognormal ROS Statistics Using Imputed Non-Detects

Mean in Original Scale	1.052	Mean in Log Scale	-5.928
SD in Original Scale	9.927	SD in Log Scale	2.921
95% t UCL (assumes normality of ROS data)	2.358	95% Percentile Bootstrap UCL	2.553
95% BCA Bootstrap UCL	3.544	95% Bootstrap t UCL	31.43
95% H-UCL (Log ROS)	0.54		

UCLs using Lognormal Distribution and KM Estimates when Detected data are Lognormally Distributed

KM Mean (logged)	-5.92	95% H-UCL (KM -Log)	1.588
KM SD (logged)	3.206	95% Critical H Value (KM-Log)	4.859
KM Standard Error of Mean (logged)	0.383		

DL/2 Statistics

DL/2 Normal		DL/2 Log-Transformed	
Mean in Original Scale	1.498	Mean in Log Scale	-3.318
SD in Original Scale	10.25	SD in Log Scale	2.779
95% t UCL (Assumes normality)	2.847	95% H-Stat UCL	4.463

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Detected Data appear Lognormal Distributed at 5% Significance Level

Suggested UCL to Use

97.5% KM (Chebyshev) UCL 6.035

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Approximate Chi Square Value (28.42, α)	17.26	Adjusted Chi Square Value (28.42, β)	17.17
95% Gamma Approximate KM-UCL (use when n>=50)	17.21	95% Gamma Adjusted KM-UCL (use when n<50)	17.29

Gamma (KM) may not be used when k hat (KM) is < 0.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% Gamma Approximate KM-UCL (use when $n \geq 50$)	76.08	95% Gamma Adjusted KM-UCL (use when $n < 50$)	108.3

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

97.5% KM (Chebyshev) UCL 0.676

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

ATTACHMENT A
ESTIMATION OF REPRESENTATIVE EXPOSURE POINT CONCENTRATIONS FOR CHEMICALS OF
POTENTIAL CONCERN IN OFF-SITE PUBLIC ROW SOIL (0-10 FEET BGS) - PROUCL OUTPUT
Former Santa Rosa MGP Site
Santa Rosa, California

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma Statistics on Detected Data Only

k hat (MLE)	0.539	k star (bias corrected MLE)	0.502
Theta hat (MLE)	0.276	Theta star (bias corrected MLE)	0.296
nu hat (MLE)	28.03	nu star (bias corrected)	26.13
MLE Mean (bias corrected)	0.149	MLE Sd (bias corrected)	0.21

Gamma Kaplan-Meier (KM) Statistics

k hat (KM)	0.0776	nu hat (KM)	15.22
Approximate Chi Square Value (15.22, α)	7.413	Adjusted Chi Square Value (15.22, β)	7.331
95% Gamma Approximate KM-UCL (use when n>=50)	0.0972	95% Gamma Adjusted KM-UCL (use when n<50)	0.0983

Gamma (KM) may not be used when k hat (KM) is < 0.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

k hat (KM)	0.02	nu hat (KM)	3.927
Approximate Chi Square Value (3.93, α)	0.693	Adjusted Chi Square Value (3.93, β)	0.674
95% Gamma Approximate KM-UCL (use when n>=50)	0.285	95% Gamma Adjusted KM-UCL (use when n<50)	0.293

Gamma (KM) may not be used when k hat (KM) is < 0.1

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free UCL Statistics

Detected Data appear Approximate Lognormal Distributed at 5% Significance Level

Suggested UCL to Use

95% KM (Chebyshev) UCL 0.213

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.008	Mean	6.763
Maximum	630	Median	0.01

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Data do not follow a Discernible Distribution at 5% Significance Level

Suggested UCL to Use

97.5% KM (Chebyshev) UCL	47.04
--------------------------	-------

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

95% Student's-t UCL	33.4	or 95% Modified-t UCL	33.48
or 95% H-UCL	33.3		

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002) and Singh and Singh (2003). However, simulations results will not cover all Real World data sets.

For additional insight the user may want to consult a statistician.

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.

H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.

It is therefore recommended to avoid the use of H-statistic based 95% UCLs.

Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Theta hat (MLE)	3.9645E-5	Theta star (bias corrected MLE)	4.4208E-5
nu hat (MLE)	5892	nu star (bias corrected)	5284
MLE Mean (bias corrected)	0.00403	MLE Sd (bias corrected)	4.2196E-4

Gamma Kaplan-Meier (KM) Statistics

k hat (KM)	57.94	nu hat (KM)	5562
Approximate Chi Square Value (N/A, α)	5389	Adjusted Chi Square Value (N/A, β)	5384
95% Gamma Approximate KM-UCL (use when $n \geq 50$)	0.00405	95% Gamma Adjusted KM-UCL (use when $n < 50$)	0.00405

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detected data is small such as < 0.1

For such situations, GROS method tends to yield inflated values of UCLs and BTVs

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.003	Mean	0.00639
Maximum	0.01	Median	0.004
SD	0.00297	CV	0.465
k hat (MLE)	4.93	k star (bias corrected MLE)	4.636
Theta hat (MLE)	0.0013	Theta star (bias corrected MLE)	0.00138
nu hat (MLE)	473.3	nu star (bias corrected)	445.1
MLE Mean (bias corrected)	0.00639	MLE Sd (bias corrected)	0.00297

ATTACHMENT A
ESTIMATION OF REPRESENTATIVE EXPOSURE POINT CONCENTRATIONS FOR CHEMICALS OF
POTENTIAL CONCERN IN OFF-SITE PUBLIC ROW SOIL (0-10 FEET BGS) - PROUCL OUTPUT
Former Santa Rosa MGP Site
Santa Rosa, California

Approximate Chi Square Value (445.06, α)	397.1	Adjusted Level of Significance (β)	0.045
95% Gamma Approximate UCL (use when $n \geq 50$)	0.00716	Adjusted Chi Square Value (445.06, β)	395.8
		95% Gamma Adjusted UCL (use when $n < 50$)	0.00719

Lognormal GOF Test on Detected Observations Only

Shapiro Wilk Test Statistic	0.402	Shapiro Wilk GOF Test
5% Shapiro Wilk Critical Value	0.926	Detected Data Not Lognormal at 5% Significance Level
Lilliefors Test Statistic	0.473	Lilliefors GOF Test
5% Lilliefors Critical Value	0.165	Detected Data Not Lognormal at 5% Significance Level

Detected Data Not Lognormal at 5% Significance Level

Lognormal ROS Statistics Using Imputed Non-Detects

Mean in Original Scale	0.00398	Mean in Log Scale	-5.529
SD in Original Scale	3.7100E-4	SD in Log Scale	0.0839
95% t UCL (assumes normality of ROS data)	0.00407	95% Percentile Bootstrap UCL	0.00408
95% BCA Bootstrap UCL	0.00411	95% Bootstrap t UCL	0.00411
95% H-UCL (Log ROS)	N/A		

DL/2 Statistics

DL/2 Normal		DL/2 Log-Transformed	
Mean in Original Scale	0.00399	Mean in Log Scale	-5.583
SD in Original Scale	0.0014	SD in Log Scale	0.359
95% t UCL (Assumes normality)	0.00433	95% H-Stat UCL	0.00441

DL/2 is not a recommended method, provided for comparisons and historical reasons

Nonparametric Distribution Free UCL Statistics

Data do not follow a Discernible Distribution at 5% Significance Level

Suggested UCL to Use

95% KM (BCA) UCL N/A

Warning: One or more Recommended UCL(s) not available!

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Chemical (zinc)

General Statistics

Total Number of Observations	42	Number of Distinct Observations	30
		Number of Missing Observations	0
Minimum	21	Mean	91.78
Maximum	1400	Median	34
SD	217	Std. Error of Mean	33.48
Coefficient of Variation	2.364	Skewness	5.653

Normal GOF Test

Shapiro Wilk Test Statistic	0.32	Shapiro Wilk GOF Test
5% Shapiro Wilk Critical Value	0.942	Data Not Normal at 5% Significance Level
Lilliefors Test Statistic	0.375	Lilliefors GOF Test
5% Lilliefors Critical Value	0.137	Data Not Normal at 5% Significance Level

Data Not Normal at 5% Significance Level

Assuming Normal Distribution
